> no work is done. You'll need to prove the first part of the sentence in
> order to show the second part to be true.

Your ignorance is showing, Jim. It takes absolutely no work to
transform impedances because those impedances are virtual and
meet the IEEE Dictionary definition (B) for "impedance" which
requires zero work.

It might be better to say the reflected energy is performing
a "function" which requires no work (possibly a lot like being
a physics professor). :-)

> 73, Cecil http://www.w5dxp.com

No Cedcil I don't have a problem with vectors but apparently those
that follow the sciences of electricity do. From time memorial
electrical engineers have used iron filings to determine
the field lines of an inductor. Yet at the same time we do NOT use a
ferrous material for antennas.Thus when using E and H in radiation
calculations one must determine the the phases of both that are
applicable to the material used. Where the books of old place the EH
vector at the pont of radiation as 90 degrees to each other this can
only be seen as representitive of a ferrous field, where as, a
diamagnetic field vector is exactly the phase of the electric field
vector, putting aside for the moment the "curl" vector. When
considering a radiative circuit one must fully understand that the
current creating the field
is the instant expiration of a capacitor. When a inductance accepts
such energy to generate its field one must determine the material used
to ascertain the true shape of the field. It is no coincidence that a
diamagnetic field is noted for its levitation properties that a
ferrous material cannot supply.So instead of accepting formulae where
a magnetic field is assumed to be consistant the same for all
materials for all materials one must understand that this assumption
is not correct even tho it has consumed the sciences of today which
has forced the generation of the new sciences of the day. It is time
the books were redwritten to reflect the true workings of nature
around which Newtons laws still stands.
My two penny worth from a mechanical engineer.
Best regards as always
Art Unwin KB9MZ....XG(uk)

What is even more amazing is that someone in CA can
reply to my TX posting before I posted it. :-)

Reminds me of a tale. A guy in Abilene, TX was taking
a bus to Hobbs, NM. It left at 12:00 and got there
at 12:10. When asked if he wanted a ticket, the guy
replied, "No, but if you don't mind, I'd like to watch
that sucker dig out when it leaves."

>Does anyone have any solutions to this problem?

Hi John,

From Rain City (Seattle). I did this in a Maple forest. I did mine
with pulleys top and bottom with a continuous loop like a flag pole. I
then passed up another pulley on that loop for the runner holding the
wire antenna. Then I made sure it would break at the wire connection,
not the rope. The continuous loop always gave me access to the pulley
that the antenna rope passed through. I used a two liter bottle of
water to ballast and tension the wire pulley system.

Think FUSE. Choose your point of failure, don't let it happen.

Stop right there. The type of resonant circuit depends upon length and
construction of the antenna. My 20th edition of The ARRL Antenna Book
says on page 2-6:
"Near its half-wave resonant frequency, a center-fed lamba/2 dipole
exhibits much the same characteristics as
a coventonal series-resonant circuit."

I live near Lake Tahoe and tree limbs are not the only problem so like Richard I use 3" HD closed pulleys running 1/4" Nylon rope to my end insulators and a 8x8x16" cement block at the bottom of each end for tension. Have found that good quality 12 GA Copper Clad steel wire is all but impossible to break. It might sag but get the Snow, Ice or Limb off and back up it goes.
BTW: I have used a wrist-rocket/slingshot and spinning reel to shoot accurately over limbs or the tops of 200' Pines.
Good Luck. K6ME

Just be sure the two ropes coming off the pulley don't gett tangled up with
each other. Mine did

>I used a two liter bottle of

This also works. As the tree sways back and forth, you don't want the wire
to keep moving. I brought the fixed end of the rope some distance from the
tree, and fastened it to half of a cinder block laying on the ground. The
cinder block will move to give you slack, but not move back when the branch
moves in the other direction.

It appears that we have reached a Eureka moment: The secret for the mysterious increase in gain of the 160-m, time-variant Gaussian, diamagnetic, cosmic-particle-levitating, compact, full-wave, tank circuit, tilted antenna in equilibrium that has been described as allegedly installed on top of a short tower has been uncovered. Such gain might be optimized by rotating the the 160-m, time-variant Gaussian, diamagnetic, cosmic-particle-levitating, compact, full-wave, tank circuit, tilted antenna in equilibrium to a sweet spot in the vicinity of the randomly located conductors that increases the efficiency of the coupling. Great detective work Richard. Downside is that we will have to wait a little bit longer for someone else to solve the unified field theory.

I've yet to advance any claims for an astounding new concept in the field of antennas, "John". I'm always interested in the theoretical. Most of my knowledge of antennas is in the practical. I don't feel as if you are one who could teach me anything I don't already know on the subject.

My exposure to you here and elsewhere reveals you to be an anonymous fellow who boasts of 5KW amplifiers and of using high power on the Citizens Band. You claim to be a teacher of some sort, but your English skills are at the high school level and your knowledge of punctuation is minimal.

I've often used window sash weights. There isn't much call for 'em
these days and they can often be found at yard sales and flea markets
for next to nothing. If you can't find them, try using a quart milk
carton filled with concrete mix. After you've filled the container with

the concrete, place a large fender washer on the end of a three or four inch long eye bolt, add a nut and stick it in the concrete. A pencil through the eye will hold it in position until the concrete cures.

Afterward, it is simple to peel away the waxed paper carton. The concrete can be painted some neutral color.

Install continuous loops through all your pulleys rather than
"halyards". Hauling one side of the loop hoists the insulator and
hauling the other side of the loop brings it back down to where you
can work on it. Regardless of the condition or fates of wires
suspended between pulleys.

An aside you might check out: Really nice pulleys:

A couple of decades ago, I experimented with the "cylinder" (don't know the correct term for it) from a screen door. This is the device which allows the door to be opened quickly and then to close slowly. There is an adjustment on it which allows this action to be speeded/slowed. I remember that I ended up with 3 or four in series. The final "fail safe" was a weight which would move to prevent damage to the antenna.

It worked until I went on to other antennas ... I am surprised no antenna manufacturer has designed a device more suitable but along the same lines.

Hi! Richard.

Yes, I already have a 3ft dia magloop 3-30megs also a 5ft square
magloop for 14-80megs..... both cover the 14meg band....
they work extremely well. and as they are virtually noiseles i hear
stations that can`t be heard on a regular wideband antenna
due to a better sn ratio, albeit, at reduced signal strength.....also,
unfortunately, with reduced transmission levels.....
(very good listening antennas).

That`s why i need a larger, lower `Q` antenna ....which will also
fit in my garden space to t/x on.....

I like 20 meters a lot running Slowscan, Hampal and Digital Voice.

Regards..

Len....G6ZSG......

You are right, of course. I've been retired for a decade now and forgot what work was. :-) Work can have the dimensions of joules. Reflected power is in joules/sec. The joules in the reflected wave is equal to the reflected power times the length of the transmission line in seconds.

So far neither the performance of Art's 160-m antenna, nor the claims he makes for its underlying physics have been publicly proven by scientific methods.

> All experience based on yesterdays knowledge which does
> not allow for new discoveries, because you are an expert
> and there is nothing for you to learn that you do not know already.

Not at all. Discoveries continue to be made in the sciences. And when they are, they are supported by natural law, are thoroughly documented and presented in such a context, and those discoveries and their results can be replicated by others.

If Art could followed that course he would get a better response to his concepts, if he still chose to present them.

> it.

It is a gross confusion of cause and effect to say:
"If two waves superpose to zero, those two waves
don't exist." If the component waves being emitted
by a Yagi antenna don't exist, then it is a waste
of time and money to put up a Yagi antenna.

Maybe you should notify HP that they are wasting their
time publishing the following equation since s11*a1
and s12*a2 don't exist.

b1 = s11*a1 + s12*a2 = 0

That equation does *not* imply that s11*a1 and s12*a2
must equal zero. In fact those non-zero values are easy
to calculate. Square each and you have the power associated
with each of those components.

The irradiance equation from optical physics can be
derived by squaring the s-parameter normalized voltage
equation. Since (a1*a2) is a phasor term in that equation,
the phase angle between a1 and a2 must be included in the
result.

i have a very small 160m antenna that 'works'. How well art's antenna
works, and in his case, the more important question is how he can prove or
demonstrate to someone that the cosmic equilibrium static particles that
levitate from it when he uses it are the real questions.

I haven't had any problems using a weight, through a pulley, to hold a wire antenna up. If that weight really gets to bouncing on the end of that line, I figure it isn't quite heavy enough, or the tree is moving so much the antenna isn't gonna stay up anyway (just hope the tree does).

Roy Lewallen wrote:
"Thus we see that the (quarter wavelength) folded dipole exhibits the qualities of a shunt-tuned circuit and has a terminal resistance value Ra of high magnitude."

Yes, my copy of Bailey says the same. I got the 6000 ohms from page 509 in the catalog section where large diameter rods were used for the 200 MHz antenna.

Looking at Bailey`s page 508, Fig. 8-14, it seems a 1/2-wavelength perimeter can be opened into a loop instead of a folded dipole and iits radiation resistannce drops to about 5 ohms. This is a mixed blessing because as Roy says, "There`s no free lunch". A loop configuration does not lower the loss resistance in the conductor and this will extract a larger percentage of the energy fed to the conductor with a lower radiation resistance.

A closed loop has an inductive reactance at frequencies below first resonance (when the wire perimeter is almost 1/2-wavelength). This reactance can be compensated with a simple low loss series capacitor. It is unfortunate to not have room for a straight radiator.

Best regards, Richard Harrison, KB5WZI

Hi Len (Lee?),

Are these commercial loops with substantial conductors (well beyond
what would be called wire)? If so, then pushing them into 80M is
going to be a trick unless the 3-30MHz model in fact works. If it
does not, it needs more capacitance, and that is going to be a loss
leader if you try to add any.

The only other limitation in the 20M band would be how high are they?

>That`s why i need a larger, lower `Q` antenna ....which will also

>
>I like 20 meters a lot running Slowscan, Hampal and Digital Voice.

As far as 20M goes, your garden is long enough for a conventional
dipole - provided you have the support, and the direction favors your
need. If not, it seems unlikely you will gain anything over the
magloops. (Go for more height.)

Define "works"...
Nearly anything will radiate to some extent. Even many dummy loads
and light bulbs. How much better than a dummy load would be the real
issue in the case of his small antenna.
If he did not test the antenna according to accepted methods commonly
used, this would not matter to you?
At the very least he could put up a full sized reference dipole,
chase the spiders from the innerds of his radio, and compare
them. He doesn't even have to actually transmit to do these simple
comparisons for himself.
But in order to prove an antenna to the big wide world out there, he's
going to need to test it on an excepted antenna test range, and then
provide all the data if he wants anyone pay much attention.
This would apply to anyone, not just Art.
It seems you would except his word on it, without actually seeing any
proof of this claimed full sized lunch from a dinky radiator.
That would be weird to me.

Alan,

Have you ever come across the following paper by Harold Aspden? It is fairly
wild and might give you some concepts to consider.

Derek.
I thought you would like to know that I made another 160M antenna
today which isvery much smaller than the one I have on my tower. If
somebody takes you up on your bet you will be able to afford a trip to
Central Illinois and I will give it to you to take home to Sydney or
what ever.
It is compact enough for carry on luggage so it will not be a
problem.It is below zero temps
here at the moment but it has resonant points either side of 160M on
the ground one of which is 200 ohms the other is outside the scope of
my MFJ 259 . I could measure it on a SA if I have to but it is best
now to wait until spring unless a bet is made. When it goes up one of
the resonant points will move to 160M.
My next antenna to make will be small enough to put on a dinner plate
for the broadcast band but I really do need to fix the plasma tv as
the wife likes watching the tennis from down under on the big TV. I
believe it got a lightning pulse from the cable line so I need to
change out a relay or a transistor amplifier /switch to get it going
again. Small relays are known to weld anf the front end transisters
are not made to handle a high current, hopefully it is one of the two.
My Best Regards and many thanks for your confidence in my honesty.

Maybe to you, but some people on this newsgroup have alluded to my honesty.
I never played hooky from school in my lifetime(well maybe a couple of times)
I am not a redneck so I had no fears that education would deteriate my inbuilt intelligence
like you did. So I was able to tuck a few years under my belt until a free trip came about for my family and I to Central Illinois. Didn't bargain on staying so I had to sell my house in London for a song. It now costs so much I can't hardly afford to buy it back! By the way the U.S. also subsidized the trip over, so your tax money was really appreciated.
A former immigrant who made so much money over here that he stayed.
Art Unwin KB9MZ....XG(uk)

PS.
The company paid for trips to Italy,Germany,Swiss Alps and England as well as Hispanola,PR and other Islands in the Carabbian while I was helping the company to move manufacturing offshore. Ofcourse the engineering jobs were transfered later and I was real sorry to see the guys go.Now I am retired and rarely go overseas, it is cheaper to pay relatives to do the travelling.

Congratulations. Universal scientific accolades, a place in history with the Great Masters whose names you often quote, and huge financial rewards may be in order for you and/or the nominated beneficiaries of your estate, "art."

But first, what are the proven/provable radiation characteristics of your new 160-m antenna design as you believe them to be, in comparison to those of a conventional, proven 1/4-wave vertical monopole with a broadcast-type, radial ground system?

Please show your work.

Otherwise...

RF

PS: Derek, "JS," and any other of art's groupies -- please feel free to chime in.

Len, Lee Leon Leonard or Leonardo .....no problem as the birth name is
Leonard...

> Are these commercial loops with substantial conductors (well beyond
> what would be called wire)?

HOMEBREW!!! .....3ft dia loop, (10 ft circumference) 3/8" tube -
can be persuaded to 80meters ....
HOMEBREW!!! ......5`.0" square (20ft circumference) loop 3/4" tube -
can persuade it to 160meters.

> If so, then pushing them into 80M is

No problem....80meters isn`t the problem ! - they work!

> going to be a trick unless the 3-30MHz model in fact works.

It works well in the design freq of 3 - 30 megs....can work lower at higher
`Q`
.......higher `Q` not good!

> If it does not, it needs more capacitance, and that is going to be a loss
> leader if you try to add any.

Agreed.

> The only other limitation in the 20M band would be how high are they?

Vertical - ground level for vertically polarised ground wave- with
directivity.
Horizontal - 30ft for horizontal `omni directional` polarization - less
gain
than a straight, horizontal dipole at the same height.

> >That`s why i need a larger, lower `Q` antenna ....which will also
> >fit in my garden space to t/x on.....

> dipole - provided you have the support, and the direction favors your
> need. If not, it seems unlikely you will gain anything over the
> magloops.

>>>>>>(Go for more height.)<<<<<<<

If you read the o/p, you wouldn`t question everything i have already
stated Richard!!!

I don`t want a fixed dipole at low height!! i want a rotary dipole on the
top
of my tower (mast)....i am aware i can fit a 33foot fixed, wire dipole into
a
35foot garden, lengthwise, but the length of my garden runs east/west so the
dipole would fire north/south - not good..... the magloops receive very
well,
with lower noise than a regular antenna, i can hear stations i wouldn`t
normally
hear on a regular antenna, plus, a horizontal dipole, generally, has more
gain
than a horizontal omni magloop at the same height but is a noisier r/x than
the
magloop, which makes the dipole better for t/x mode....Yes?...
My garden is 14ft wide and a 14meg dipole is 33ft+, i don`t want my
neighbours
complaining when half the antenna is over their garden when i`m working east
west...hence linear loading the dipole...to shorten it!!

All i requested was a suitable design configuration for a linear loaded
halfsize
rotary dipole to go on top of the tower and my reasons why.....
not a discussion on magloops ....

I`ll go with the linear short 1/4 wave vertical layout for each leg of the
dipole,
where half the element is fed back on itself down to 6 inches from the
ground
(or, in my case, to the mast) with about 3 inch spacing of the element.

Regards.

Len ....(Lee, Leon Leonard Leonardo).....G6ZSG....

Hi Len,

Yes, but marginally. This is a double edged sword. The Q that gives
you such superlative receive characteristics is going to drive you
into CW mode in, perhaps, 80M, and certainly in 160M - not to speak of
the critical tuning. You have the height, something I missed from the
distraction of 20 other unrelated postings to this thread, so you have
solutions and that height is both far and away sufficient for the
upper HF, and more to the matter, the best practical solution for your
neighborhood. As to the antenna construction, you have answered the
Ohmic losses to a considerable extent, and you are aware of the
relationship of Ohmic Loss to Radiation Resistance. You would do well
to report to the group your SWR bandwidth for several of these bands
so we can get a grasp of the actual Q. Simply for 160/80/40/20, how
many KHz between the 2:1 points?

There are a lot of pluses there, except for the high Q on low bands.
You also express in your list of negatives that you don't seem to get
out (a transmit problem).

>My garden is 14ft wide and a 14meg dipole is 33ft+, i don`t want my
>neighbours
>complaining when half the antenna is over their garden when i`m working east
>west...hence linear loading the dipole...to shorten it!!

If I recall (as you have a lot of widely separate issues here), you
want to operate 20M. Your garden as you state here is too narrow (it
is) for the direction you desire. An efficient design is going to

demand end loading aka top hat style (long radial spokes at the end of each arm of the dipole you want).The end loads, if sufficiently developed (and not a simple installation, I suspect) could do it without further loading with a coil somewhere (and if it were anywhere, the good advice from years of reporting here would indicate that it would be one half to two thirds out and away from the feed point, on both sides). Another alternative is an inverted V which would seem to be within your capacity (depends on where the tower is sited).

As your interests span 20 down to 80 and Q intrudes into the bandwidth you desire at the longer wavelengths, then lowering Q would only drive down your efficiency and increase your complaint of getting out. It seems you are rapidly moving away from the loops. You might (if you can interpret the technical comments) try Arthur's contra-wound inventions. No doubt, they too would make good receive antennas, and the proximity of windings would lower Q, but this would come at a severe loss of gain and sensitivity. A receiver has enough gain to make up for this loss, but your transmitter is forever crippled with the introduction of both Ohmic loss and its loss boost due to tightly coupled currents.

A larger diameter antenna is called for if you are sticking with loops, but that is probably unmanageable.

Another breed of loop, the halfwave open loop allows you to build an omni horizontal polarized antenna in a small area, but we now enter into other issues you have not discussed. What resources, other than the tower, are available to you for supporting the linear loaded dipole you seek? If you have four support points, your garden size is not unsuited to a full half wave design, there are no Q issues, no efficiency issues - except for matching to a 5 Ohm load. What can I say? Compromise antennas demand care and feeding.

You lost me entirely here. You want a horizontal dipole, and you will build a closely coupled vertical system that will rotate where half the element is within 6 inches of ground? Too much is left unsaid in this description. Is your tower guyed? Freestanding? You are using the mast (tower?) as half the antenna? Is the mast (tower?) grounded?

This sounds like you are top feeding a vertical quarterwave open transmission line that rotates around one element. If so, your feed line is going to really become a nightmare of isolation. It will show varying horizontal/vertical directivity to a loss of 10dB in any direction - if you can match to the near short circuit conditions at the feed point.

I don't think this is what you mean, but what you describe is vague.

Get lost. You are not in the circle of a need to know,only the heckler
list.
You just can't handle the truth as I told you a ground plane is not
necessary.
They just supply unwanted noise anyway compared to a antenna away from
the ground surface.
If you want to be part of a bet then call Australia as I will not be
getting your posts anymore
because they are unproductive. But don't let that stop you in
arranging the bet to prove your points as I will still cooperate in
the adjudication.

At which point during your sucking at the teat of the US taxpayer did insanity enter into the equation?

>A former immigrant who made so much money over here that he stayed.

Of course you stayed, they *all* stay. In my travels worldwide I am often able to gain the confidence of people in other countries to the point that they eventually say the negative things about the US that are deep seated in their minds. At the same time, when I was empowered to offer the prospect of green cards (as I have been a few times, and did,), without exception the response was overwhelmingly positive. So, if the US is so shitty, why do they want to come here? The only answer can be that their home countries are shittier, which in fact they always are (including any place in London that art could afford to live in). The intent of art's post is to insult and enrage Americans on this thread by saying, take all the foreign aid that you, in your stupidity and ignorance, gave to me and my family and shove it up in your idiot country's posterior. But, lest art's groupies become confused, remember that arthur stayed here by choice and he is quite happy

here, building broadcast antennas that fit on dinner plates; it might just work after all, in the same country where it was possible to generate such great profits for the inventor of the pet rock. Opportunities abound.

Tom,
Don't concern yourself with me. People who have something to offer
have my full attention.
This guy is acting like a baby and trying to censor me and my work,
but he can't do that if he himself has no credability. People on the
sidelines watching obviously are interested in antennas and can easily
spot those of no interest. He would be better of argueing about
standing/travelling waves which is garanteed employment for at least
five more years and where
Cecil will reply to him until hell freezes over on the subject. I may
put this new antenna
if I get brave enough to go out in the cold but then I may wait for
spring and concentrate on other things. Seems like people think I am
trying to sell them something, when I am not. I am retired and am not
interested in actively pursueing monetary rewards. I pay for a patent
as a record of my work. If money is offered I will take it to pay for
my other pursuits and I have many to complete.
Thanks for the effort anyway but let their comments slide over since
they are meaningless.
Best regards
Art Unwin...KB9MZ...xg(uk)

20 foot circumference is the longest magloop for 14megs operation!!!
That is with 90% efficiency...

I`m not building a vertical !!!

> I don't think this is what you mean, but what you describe is vague.

Probably.
Imagine a half wave dipole with each leg folded back on itself
effectively becoming half its original physical length but still
the original electrical length, each leg is like a long thin letter
`U` ..like a folded dipole that has been cut open circuit opposite
the feed point...I shouldn`t have mentioned a vertical because
it mis-lead you, it was meant just to describe the configuration
of the dipole legs.

Cheers.

Len.......G6ZSG.......

As I have said many times, free speech is a right.The downside is that
it
portrays the manner of man who takes hold of that freedom.
When you stated I was dishonest it hurt, but then I realized that now
I
knew the manner of the man in question. When a door is slammed shut
in your face another always opens so that the light may enter. As Dr
King would say "I have seen the light"
and no doubt many others also have seen the light. I am not a liar and
some are willing to bet on it while you, the accuser, have turned
tail.

Hi Len,

This is more tenable. A satisfactory dipole, no horrendous loss due
to counter winding feed. If you can hoist a beam, about 19 feet wide,
with two wires connected at the ends and returning below it about 4
inches coming back within 4 inches of the beam above; then you stand a
chance, provided you can match to about a 7 Ohm load.

I presume your description follows something like (in fixed font):

Of course, our best defense is to use our allocated bands to the maximum. As long as there is a large installed base of ham equipment and the hams use it, the government is less likely to take those bands away, no matter how much lobbying occurs because they know that those bands will never be free of gross interference. At worst case, the "carpetbaggers" would be driven away by those who have invested money in their equipment. Knowledge of this MAD scenario is our best defense. Imagine what would happen if they tried to give 11m to a private company; I wouldn't bet on it succeeding. Not that I for a moment would *ever* advocate illegal operation of any kind.

Then it should be a simple matter for you to actually measure the canceled waves and their energy in order to prove everyone wrong once and for all.

And yet when b1=0, they refuse to deliver any. It doesn't seem to lend much support for your claim.

> 73, Cecil http://www.w5dxp.com

None of the well proven methods shows a need for there to be any energy in canceled, non-existant waves. HP would certainly never affiliate themselves with a claim that there's energy associated with waves that don't exist. The irradiance equation with all its "phasor terms" is no help either. Where there is no irradiance, there is no EM energy. Even Yagi antennas fail to radiate energy from their null points. The only person I've ever seen claiming that there is energy in non-existant waves is you, Cecil. On it's face, the idea is ludicrous. And apparently you don't even find beauty in the fact that, with no energy traveling in the direction of cancelled waves, there is no need to invent a "4th mechanism of reflection" in order to conserve

that energy and get it moving in its correct direction of travel. As a bonus, there is no need for religious beliefs that interference and wave interaction cause waves to change direction. Accepting this would of course mean yet another delay in the quest for martyrdom.

What about giving 220-222 mHz to UPS, who then decided not to use it?

Geoff.

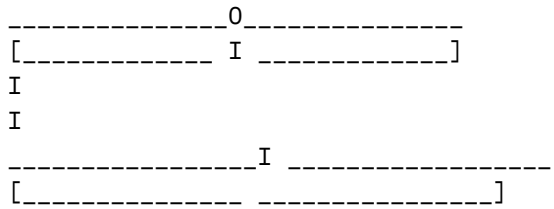
Yes. Richard, you have it now...i was mainly concerned about the spacing
of the foldback from the parent element as i have seen much more exotic
layouts using 3 and four foldbacks using 400ohm ribbon feeder for the
element which i might try for 80 and 160, but i`ll make those using spaced
single wire dipoles rather than utilise a rigid rotatable ten meter dipole
and
a couple of lengths of wire..maybe i can do the same again for a reflector??



Regards....

Don't we as a country have more to worry about than worrying about if Romney feels that hams aren't necessarily needed? What about issues like social security, foreign policy, immigration, etc. Where does Romney stand on these issues? To decide to vote or not vote for any candidate based on their view of ham radio is a bit narrow minded perhaps?

I have just got around to reading just the intro
of the above URL. Later I will digest the rest of
the lesson.
What struck me was how deftly the author pointed out
where pseudo experts have dominated science thru the ages
such that it reflects the poles of the many led by the few.
It shows time and time again that science is a popularity
contest where the so called "in crowd" of of self rightious
people have been able to thwat the advances of science of
the past centuries. Gallilao comes to mind as does Green
of Nottingham and Heavieside of Clapton and ofcourse my favorite
Gauss. We are seeing the same thing here on this newsgroup
where passed tenents are held on to the death by those
addicted to the passed. Naturally I think about my own case.
I presented a trail of science where each step can be examined in
depth
on Googles when reading the achievements of others.
There is not one point on the trail that prior science does not
repute.
It fills a void with respect to radiation where presently there
is nothing else presented to fill this gap of knoweledge.
Yet we can see how humans react to change with out a morsel
of evidence to contradict the new are able to gather a baying crowd
similar to that around madame Guillotine to view the death of nobles.
Ofcourse at that time academia had not closed its society off
from the outside where now they are better equipped against the poll
makers
such that the only efforts left to derail in science are those
generated outside the
academic world and also judged by those who are also excluded by the
closed society
as a unproven value. Vincent was different. He generated his skunk
works from the inside of academia who were desperate to include
themselves into the closed.science of academia, Where they could
supply information that would not and does not pass the time of day in
academia.
I read a tale once that a man hid from facts by hiding in a garbage

can where he suddenly realised he was closed off from all the worries of the world. Where the temperature was warm and food tho spoiled was available for the picking. Ofcourse there was the smell but what did it really matter as nobody else was around that could smell and thus insult him.
In this group there is evidence that some of its members have emerged from their former places of confort and thus show that even in speech does the former odour prevail.
Humans must get away from this syndrome of resistance to change and regain its inherrant inquisitiveness.
Very best regards to all

Do you suppose that red blood cells look down their noses at white blood cells? After all, there are far more red blood cells than white blood cells. Numbers alone would indicate that they are superior. Perhaps the white blood cells feel that they are superior because there are fewer of them. Plus, they have the noblest task of all, that of defending the world/body.

Without either type, our bodies would cease to function.

So it is with various types of people. We need them all.
Each have their function. None are expendable.

Ed, NM2K

Yes. But when they over estimate their abilities in areas outside
their field of expertise you can expect problems.
Both a set of gears as well as a wrench each have superb qualities.
Let the wrench place itself between the grinding teeth of gears
then
all progress comes to a halt

Hi Len,

As for going lower to 80M using 3 or more foldbacks (for the simpler
dipole) to keep it in your garden. Stick with your mag loops, because
it doesn't get any better.

Using 3 foldbacks for 80M (and the antenna is too wide for your
garden) will give you a 10 KHz bandwidth at the 2:1 SWR points. Making
the antenna smaller to fit, drives up the Q. 160M only portends worse
Q (from your point of view).

A small dipole, like a small loop, either are going to be hi Q if they
are to be efficient.

YOW!!!

You are now getting quite elaborate. You can accomplish this, with
great care, and if you have the patience to raise and lower this half
a dozen times or more to get it right.

jimkelleyamps@gmail.com wrote:
> Then it should be a simple matter for you to actually measure the
> canceled waves and their energy in order to prove everyone wrong once
> and for all.

The energy in the canceled waves is why the forward
power is often greater than the source power. As the
Melles-Groit web page says:

http://www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and the
thickness of the film are such that a phase difference exists
between reflections of p, then reflected wavefronts interfere
destructively, and overall reflected intensity is a minimum.
If the two reflections are of equal amplitude, then this
amplitude (and hence intensity) minimum will be zero."

When it is zero, total destructive interference and wave
cancellation has occurred.

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity
will appear as enhanced intensity in the transmitted beam. The
sum of the reflected and transmitted beam intensities is always
equal to the incident intensity. THIS IMPORTANT FACT HAS BEEN
CONFIRMED EXPERIMENTALLY." (emphasis mine)

Melles-Groit says it has been confirmed experimentally.
That's good enough for me. What it is about the Melles-Groit
web page that you don't understand?

> And yet when b1=0, they refuse to deliver any.

No, the the energy is delivered (redistributed) in the
opposite direction. What is it about the FSU web page
that you don't understand?

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit

constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

> None of the well proven methods shows a need for there to be any
> energy in canceled, non-existant waves.

The Melles-Groit web page says the energy in the canceled waves
"appears as enhanced intensity in the transmitted beam" (forward wave).

The FSU web page says the energy in the canceled waves is
"redistributed to regions that permit constructive interference"
(forward wave).

That's good enough for me.

It was my understanding when it was first brought up that what he meant was they the government agencies were fully able to handle there own comm needs. It would have truly been udder stupidity on his part for him to have meant anything else. It is true that the amateur radio community is needed less and less even though we are more than willing and able to fill the need. A very small case in point: A charity walk/run used to be handled by the local ham radio clubs providing emergency communication and coordination via handheld radios and the local repeaters. This past year it was handled by the Girl Scouts using cell phones.

Jimmie

wrote:

>The only person I've ever seen claiming that there is energy
>in non-existant waves is you, Cecil.

Hi Jim,

That's not strictly true. I for one have always maintained there is energy where it cancels, it is also somewhere else when it adds. On the other hand if it is no where else to add, that seems to put an end to it. Like a draw match in a tug of war, the rope may not be moving, but its tension is obvious by the nulled energies.

>On it's face, the idea is ludicrous.

Perhaps at the myopic scale of picking a point to the exclusion of examining all points illuminated (radiated, or otherwise excited) by two sources.

As for the non-existence of waves, I would read this as the resultant combination of two waves exhibiting a null at a locality. This then argues: What is a wave? Sorry to bring up that zombie topic as it will no doubt lead to Cecilaborations he constructs only for idle diversion - that is not my fault, and I certainly don't follow his narcissistic meanderings with as much attachment as you or Keith or Gene (or Art's fawning, but puzzled adoration). Clearly you cannot have a wave (3D by its very nature) at a 1D point. The absurd extension of the argument would then deny a wave exists anywhere because all singularities examined lack dimension.

Let's simply divorce the second source and look at the dipole. It clearly is a source of energy, no one is going to deny that I hope (OK, Cecil will as this post is draining the numbers on his celebrity status). We can still discuss fields (includes DC then) or waves (extending to AC/RF). We can combine them, every text does this in the first chapter. We find a line bisecting the dipole with a null response. An infinitesimal point residing in the infinite bisecting plane can't tell the difference between a null and no field/wave certainly. Is energy non-existent? The tug of war informs us otherwise. Turn off the dipole, and you win the argument of non-existent energy - but the rope collapses to the ground, falling out of its 2D shape. Even for the tug of war, the evidence still differentiates between the two circumstances.

This non-existence blossoms into:
>Even Yagi antennas fail to radiate energy from their null points.
such is the well from which Arthur draws his inspiration.

Antennas radiate equally in all directions from all points. Nulls are
the products of the sums of those radiations at a remote point.

Cecil's MENSES challenges collapse from their own internal faults
easily enough, pursuing his illusions are not required unless this
greek chorus enjoys polluting the well to sustain the comedy.

I proved myself as a true ham today. I had this new antenna on hand
but the temperature was zero F degrees. Undaunted I went outside and
disassembled my presenst antenna and took it off the tower and then
replaced it with my replacement extra portable 160M antenna. By the
time I finished at noon the temperature has reached a balmy 12 degrees
F. Warmed myself up and the
put the MFJ259 on the line in the shack. The resistance did not go
below 20 ohms and climbed to 100 ohms at one end of the band.Swr on
the meter showed a max of 3:1 across the whole band.
I will have to wait a day or so to check it again to see if a matching
effort is required
when using the tube output of the amp which is tunable ofcourse. Now
to the wifes honey doos for the rest of the day.Again, facts are
stranger than fiction when using an antenna that is a tight squash
into a lawyers briefcase which is larger than the norm. That defies
the long held housewives tail that size is everything even tho
aperture is proportional to gain, all ofcourse based on a yagi design
which all hams are sure cannot be beaten by a smaller antenna
array.Where are the censors of the day? By the way when the WHOLE
radiator is 70foot or so away from ground the decrease in noise is
tremendous.

Regards to all
Art Unwin KB9MZ....XG(uk)

I am compelled to respond to this collection of words from which I see
a conclusion
of what is to be considered agreement or disagreement.
The wise will accept that there is disagreement and no amount of
slander is likely to change that. Because the wise retreat to the side
lines it by no means to be taken as representing anything. Where as
you little twit, are now trying to portray what you apparently knew
all along at the same time covering your words with camoflarge to
disguise your present position until more information is at hand.

Sounds like equilibrium does it? Or it is like so much of your theory
and is the non-existence of 'ment.' Is there such a thing as an
infitesmal thought in the plane bisecting bafflegab?

Wrong Art, the very purpose that the link was posted in this thread was to encourage alternative concepts to those developed in the 1800's, 1904, 1905 and the 1930's.

There may indeed be a case for the Aether; personally, free space is merely a concept of nothingness that only contains those parameters that the scientist tends to use in his model. In electromagnetics, free space has a characteristic impedance of Zo (377 ohms), it has permeability and permittivity which fit well into our mathematical models. How can nothingness have a characteristc impedance of 377 ohms? And today we have a little more information (much more); we have theories of exotic matter and energy that are so new that no one has really taken a second look at the old concepts and perhaps investigated for possible linkages. There may be new possible explanations for the infinite negative energy of a Dirac sea that didn't make sense in the 30's; there is only a shortage of physicists with the time and money to come up with new theories in a short time.

Art, I'm sure your response to these statements will be negative (curiously which, as in the past, actually tended to support your persistence and encourage your new ideas but oppose your lack of scientific method). Finish reading the article and understand the math. Judge for yourself if you see any chinks. But do note thar Dr. Aspden uses math and logic to make his points. He also publishes references in his paper. He leaves himself wide

open for peer review. This is the way it is properly done and completely opposite of the faith-based approach you foist upon us.

It seems that about 2 years ago, Romney made a statement concerning
Amateur Radio, and something to the effect he does not support it as a means
of communication during emergencies. As I said, this was made 2 years ago,
and is now a BIG topic for some reason. While I am not planning to vote for
him, I guess someone felt the need to bring this up, to stir up the Ham
community. Looks like it did a good job from what I've seen all over the
place now. If that's the only negative thing anyone can find, he may well
may be the top choice, but then again, that does not seem to be the reason a
person is elected to most offices...

No, 'You', I believe YOU miss the point. *Romney* said he did not like ham radio operators. Words from *his* own mouth. Period.

Please tell me why -quoting- what HE ACTUALLY SAID is a smear...and if by some stretch of the imagination, you manage to twist a direct quote around as a being a smear, well then, Romney smeared himself. Finally, are we to give him a free pass just because he said it 'x' number of (years) (weeks) (days) ago?

> Why bring up comments that are
> two years OLD, NOW?

Well, because he never retracted the statement. Presumably then, these are STILL his feelings towards hams. Again, does a negative statement he makes just 'time out' and shouldn't be quoted after a certain period of time even though he still stands by the statement? What period of time would you suggest that after which, we just ignore what he said?

You tacked your license to the wall above your MFJ259?

BTW, any directional gain means little if only a small amount
of the applied RF is radiated by the small inefficient antenna.
With such a small antenna, "gain" is the last thing you should be
worried about.
My MW receiving loops have a great f/s ratio. That does not
mean I would want to use them as transmitting antennas.. :/
Git my drift Vern?

This antenna of mine has really got you in a headlock.Your breathing is close to being cut off and there is no blood flowing to your brain such that you are so angry and can't think straight.
What on earth does this antenna mean to a red neck who brags of avoiding schooling? Is it regret of some sort? It is not a secret antenna! Sooner or later you will have the opportunity to make one yourself. Probably in time for the peak of the next sunspot cycle. But then, what use will you make of it other than talk? On the other hand I don't remember anytime referring to your antennas either for transmitting or receiving other than hearing you say, in effect, that they cam beat anything on the planet. Having never met a redneck from the mountains I can only assume that such talk is the very nature of a redneck that makes them a subject for comedy. For that you do a terrific job with respect to american humour.

Angry? Have you lost your mind? This is comedy to me.
On a personal level, I could care less about you or your
sub par developments of psuedo science.
It does bother me that you pollute the minds of
unsuspecting newbies with your bafflegab though.
Not a whole lot, but enough to where I feel compelled
to tweak your ass every once in a while.
Maybe I better quit though, as it seems that when I do
this, it cuts off the flow of blood to your brain, and you
become very angry, and can't think straight. :/

> What on earth does this antenna mean to a red neck who brags of

> antenna!

You got that right. It's not even new for that matter.
You think you are the first person to try to invent a small
perverted antenna with the performance of a full size version?
I'm curious... You and and that EH antenna guy are not
joined at the hip are you? Inquiring ponderers relish an
answer.

>Sooner or later you will have the opportunity to make one
> yourself.

Why would I want a sub par antenna when I already have
manly full size versions? You need to get out of the sun..
That 12 degrees is frying your brain...

>Probably in time for the peak of the next sunspot cycle.

I don't depend on the sunspot cycles. That's probably why
I'm usually on the lower bands. My manly full size antennas
don't hurt things either..
Most any sub par design can me made to "work" on the higher
HF bands with enough efficiency to fool people who have never

tried a full size version.

>But
> then, what use will you make of it other than talk?

I agree. I already have enough dummy loads as it is.
I don't need an air cooled model that is mounted on a
tower.

>On the other hand
> I don't remember anytime referring to your antennas either for
> transmitting or receiving other than hearing you say, in effect, that
> they cam beat anything on the planet.

I expect you will be able to find me saying that with a google deja
search? I have made no claims as to my antennas being the
best on the planet. I do claim to avoid elevated dummy loads
though. I admit it. Sue me.

>Having never met a redneck from
> the mountains I can only assume that such talk is the very nature of a
> redneck that makes them a subject for comedy. For that you do a

I wasn't born in the mountains, although I think such a peaceful
setting would be nice. I was born in the downtown Dallas area.
The only mountains there are man made, and most are
glistening with lights and blinky things.
I have the dubious distinction of being born across the
street from where a certain president died a few years later.
BTW, here in the United States it's humor, not humour.
Git-R-Done Vern! Riches and fame await!
You might even end up cover boy of QST! Dang.. I'm
already impressed just thinking about it. :)

I don't understand that John!
I do remember a trip thru the mountains when we saw a sign that stated "rest area ahead" but it was a red graffity sort of sign. We kept our eyes open and later came upon it. It was an old mattress placed on the side of the road. We later came across a flea market which we intended to visit but we couldn't. There was only one huge car park that was marked for the handicap only, and it was full! We thought was mighty unfriendly. Other than that it was beautiful country. I heard one guy say I should have gone to the most afluent areas,I told him we did once and they were very friendly and invited us to a house warming. We did not go ofcourse because of the set conditions where guests had to promise to help with removing the wheels! They were not attached to the house as they had fallen off en route and landed up in a marshy area.

OOOOps
I forgot to state that the house was not actually situated in the
afluent area in its intended spot. They made a lightning descision to
live in the neigboring county where the wheels came off. The house was
close to the road and leaning at an angle but they figures with the
gouges made by the axles in the dirt woud save them some costs in
drainage and with the windows leaning towards the sky they could sun
bathe while sitting in the living room.
Brain power they proudly stated while at the same time scratching
their rear ends.
Oh, and another thing. That graffitty sign I mentioned earlier which
was a red spray paint, they sprayed that on the board after the red
paint background on the board had dried off.

John I remember now, I have seen a redneck. We came across a bunch,
all looking evil
with these huges blunderbuss type weapons. But appearances are
deceiving since they were just squirrel hunting. I asked then about
the necessity of these large wierd looking rifles but they said they
came in handy if they didn't win the race to pick up the road kill.
Taking another look at them it all seemed to make sense

Well thank you for that info. I did not know that Texas was where
rednecks came from.
How comes Cecil is so smart?

That was probably back when Clinton was in the White House.
With the sunset of the AWB, many rednecks have progressed
to more capable tools. Of course, the race for road kill still exists
in many areas, as many prefer the grainy texture of an aged
animal carcass.
If you can find a roadkill old enough to be yellow striped, you can
consider yourself a lucky man indeed, as these are considered
a delicacy by many. Road striped possums and skunks are a
special treat at the dinner table, broiled or fried.
These days, many rednecks have switched to Barret .50 cal
sniper rifles, AR-15's, TEC 9's, etc.
The old antique shotguns have been relegated for A/C use for the
mobile homes. IE: they are often used as a doorstop to hold the
front door open. For mobile home protection, the favored handgun
of the modern progressive redneck is the Desert Eagle .50 cal..

So great to see a thread that gets back to real science rather than
"Universal Laws of the Sciences" and other such rubbish.

Your analogy of course is correct. Although total energy = F dot D and the
distance is zero, one can imagine the energy in calories being burned by the
sportsmen as they strive to maintain a static situation of cancelled forces.
The force in one direction is cancelled by the force in the other direction.
The energy of the cancellation has simply been transformed into body heat.
It will continue to dissipate as body heat until there are no more calories
to burn and we go to the other static situation which is due to the
summation of 0 + (-0) = 0. The rope drops.

In the RF standing wave, the energy simply "burns" (but not as heat") into
the radiation "resistance" at the other points on the antenna. Remove it's
source of "caloric intake" and it too eventually collapses as the forward
and reverse waves attenuate to zero by radiation.

Such a simple concept but so important.

intermod problems usually pop up where there's several repeaters in close
proximity, and/or if the receiver has less than 2 IF stages.
So try in a different location - or with a better receiver.

If you are using an external amlifier, disconnect it. If you have an
amplified antenna, try something else.

This is not rocket science. If destructive interference
occurs in free space or in a transmission line, an equal
magnitude of constructive interference must occur somewhere
else in order to satisfy the conservation of energy principle.
The energy apparently"lost" during destructive interference
is simply redistributed to regions that permit constructive
interference. That is the way antenna radiation patterns
work and that is the way that waves interfere at an
impedance discontinuity in a transmission line.

http://www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and
the thickness of the film are such that a phase difference
exists between reflections of p, then reflected wavefronts
interfere destructively, and overall reflected intensity is
a minimum. If the two reflections are of equal amplitude,
then this amplitude (and hence intensity) minimum will be
zero." (Referring to 1/4 wavelength thin films.)

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity
will appear as enhanced intensity in the transmitted beam.
The sum of the reflected and transmitted beam intensities is
always equal to the incident intensity. This important fact
has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit
constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than

the spontaneous construction or destruction of light."

No. Now I have read the whole thing I can state that my work resulted
from my travels
after Gauss which lead me to my personal law that an antenna to be of
maximum efficiency must be made from a diamagnetic material which can
be any size or shape or elevation as long as it is in a state of
equilibrium. I followed thru with this on computor programs which
confirmed
with my analysis. I have since made antennas of different size,shape
and elevation which is contrary to the norm which gives me impetus to
pursue the line of thought further. Gaussian law gave me a measure of
belief that static particles were at rest on a radiator which when
coupled to a diamagnetic inductance gave particles at rest at each and
every point of the radiator an ejection at right angles to the
radiator. Googling on each and every point of that traeveling gave
credence to the parth taken.When seeing that each point of a radiator
can be considered a minute electrical circuit it can be deduced that
many samples are ejected in pattern form as is the individual
impactson the radiator itself thus creating an occillation
a phenomina that has been accepted for many a year. To see the mirror
image of these impacts on a receiving antenna does seem realistic if
all particles follow the same trajectory.
The anti gravitational effects of a diamagnetic field gives credence
to a straight line trajectory and so on. So the dust can be lihas to
be linked in some way to the solar flow of particles pattern of eleven
years which matches the turn over of the sun's poles which is known to
lead to a heavy increase in solar dust into our atmosphere and where
the earth also has additional poles based on the location of various
inate elements which tend to congregate.
These poles obviously have a connection to the earth's wobbly rotation
by movement of these various poles that could account for the curl
vector in radiation as it does with a pendulum.
So I have invented a plausable account for radiation which for myself
I consider more reasonable because of computor results and my antenna
building. So far this trail has lead to antennas that are in
equilibrium and of various shapes and elevations that matches the
conclusions found on the trail.Existing computor programs also verify
the trail.When lstening to my small antennas with their wide band

coverage and small size I feel that I should be forgiven if I consider the trail of conclusions are correct. But even if this were not so the trail taken on this premise produced a different line of thought on antennas that work exactly as predicted. So now I share my work and thoughts as a layman in this area with other laymen
and not to the any society of physics which are closed units. I am doing this to document my work for what it is and by no means put my self on the same pedestal as Einstein, Newton and others. So by sharing and explaining my thoughts with outhers I am taken to task purely because such works are only credibly submitted by those skilled in the arts within a closed circle. So it is considered wrong that I share my experiences with other laymen if it is not previously approved or meet the texts submitted by experts. So hams are now not interested in antennas and I am in errorin explaining trails taken which appear contrary to the teachings given to laymen some 50 years ago. So the options provided by laymen is to not share, to not discuss, to not sway people to rethink that which is 50 years old and to not infer that bigger is not better. If you are a contestor you must keep quiet with respect to your experiences and take them to your grave thus giving science time to stumble across it in the future as we have had enough of the re inventing of the wheel when we discover to our dismay it was written up by somebody who is now deceased. I know that people are resistant to change especially those with experiences that are repeated exactly the same for every consecutive day without change.
If this is so why is this newsgroup in existance? To keep old koots in employ? Or to hold dear all the ideals that all hams have spent to survive in their lives and keep the new at bay.
Would it not be better to converse and study each points found on the trail so others will see a chink in my logic that can lead to even better ideas. Could we review the trail and separate the good from the bad leaving a new rock on which to build? Or is it our destiny to prevent change to our ideals such when we die we take with us the reasons for this being a hobby?"
The hobby cannot survive purely on the basis on the enjoyement of slander and one upmanship.
When we have gone there will be no reason for this newsgroup or our hobby since we are destroying the very tenents that allowed us to enjoy and thus prevent those who follow us to have the same rewards.
In our younger days science profited from ham radio , but in our older days our intransience is destroying it for future generations.Why because there can be no future if we convince the young that all is known about the radiation field and they should pursue other areas to satisfy their inquisitivenes or in its absence just go with the flow of depression.
can be any size ,shape and elevation

If you are truly laughing that loudly, you ARE an idiot. I think Cecil has done an excellent job, if you have followed him (and, I cannot claim I have COMPLETELY done so), however, he has shown there ARE holes in what we "believe." And, some things don't quite "mate-up" and what we have taken for granted looks differently when under the "microscope." "Standing Waves" is but the shining example.

Your nature is just so abrasive/abusive as to be repulsive and, at least a bit, disgusting. I have to admit, I really don't understand you, or why you think simple discussion on these matters is so "dangerous." Frankly, though this all, I kind of like the "cloak-and-dagger" nature of your "cryptic" posts, however, lately them seem a bit move vicious and NOT that enjoyable.

Don't we all come away better after having had to open a smith chart and plug some equations into a calculator? Look at some software modeling, etc.?

I mean, I am at a total loss here ... you are the final oracle? Well, you and your chosen books? Get a hold on yourself man ...

Romney is a fool, but then what of the available, "news covered" candidates are not? If we were choosing them for fitness to dress a cannibals table, I guess any of 'em would serve. But to put us back on course? Restore a gov't of the people? Show ability to solve the deep economic/social problems we face? Reduce gov't? Drop back to the set of the simple ten commandments as law? Phuffft!

We all realize we are in trouble, right?

Ron Paul--2008!

India already urinates into their own water supply, do you really find it surprising the do not have a problem of possibly polluting the worlds only propagated bandwidth.

I do not think anybody has a problem with alternative high speed data provisions, just the ones that damage other information systems. Hey, if there is a BPL system that does not radiate RF, particularly in the HF and public service spectrum, I would not expect any detractors from the radio camp. BPL still has to survive being commercially viable. You really should get over this BPL fixation of yours, it is clouding your logic. It is also very much off topic, turning you into a troll.

Regards,

Chris

John Smith wrote:
> If you are truly laughing that loudly, you ARE an idiot.

Last night I did a Google search for "destructive interference
energy" and waded through about 50 web pages on the subject.
Needless to say, I found mass confusion, even among the "experts"
who are supposed to know the answer to the questions. However,
the opinions of the majority of experts matched Eugene Hecht's
concepts presented in "Optics" and the Melles-Groit and FSU web
pages that I have posted. In the absence of a local source, the
conservation of energy principle *REQUIRES* that energy "lost"
as destructive interference *MUST* appear as constructive
interference in the opposite direction in a transmission line.

We hams are usually interested in maximizing the destructive
interference toward the source, resulting in maximizing the
constructive interference toward the load. That is why we can
have 100 watts of source power with no reflected energy incident
upon the source AND 200 watts of forward power on the transmission
line. If the forward power into an impedance discontinuity
on the source side is different from the forward power out
of the impedance discontinuity on the load side, interference
has occurred with the destructive interference on one side
of the impedance discontinuity equaling the magnitude of
constructive interference on the other side.

Here is an interferometer with two outputs that can be
considered analogous to the two directions in a transmission
line. The more destructive interference that exists at the
standard output, the more constructive interference exists
at the non-standard output.

http://www.teachspin.com/instruments/moderni/experiments.shtml

"Using Dielectric Beamsplitters to find the "MISSING ENERGY"
in destructive interference - Where is the energy of the light
going in an interferometer adjusted for destructive interference?
Below is a schematic diagram showing a way to detect the non-
standard output of a Michelson interferometerï¿½the light HEADING
BACK TOWARD THE LASER SOURCE. ... Quantitative detection demonstrates
that the standard and non-standard outputs of the interferometer are
complementary. That is, when interference is destructive at the
standard output, it is constructive at the non-standard output."
(CAPITALS emphasis mine)

The Z0-match point in a transmission line with reflections is
an interferometer of sorts. When interference is destructive
toward the source, it is constructive toward the load. All
of this is explained in my Worldradio energy analysis article:

1223. Poynting Vector in Standing Waves

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-21 15:11:09 UTC
From: Gene Fuller <W4SZzzzzzz@att.net>
Message-ID: <hC2lj.153985$MJ6.107598@bgtnsc05-news.ops.worldnet.att.net>
Source record: 29143

I typically do not like to "Xerox" material to support my arguments, but I will make an exception in this case.

Very recently RRAA's very own "John Smith" included the following comment in a message.

"I think Cecil has done an excellent job, if you have followed him (and, I cannot claim I have COMPLETELY done so), however, he has shown there ARE holes in what we 'believe.' And, some things don't quite 'mate-up' and what we have taken for granted looks differently when under the 'microscope.' 'Standing Waves' is but the shining example."

Considering the source of that comment, I am not surprised. But for any others who might have been hoodwinked by the nonsense, I will try to add a bit of color. As some may recall <BG>, there has been a bit of an ongoing discussion about the nature of energy flow, or lack thereof, in standing waves.

In order to support his point about using phasors interchangeably with field vectors, Cecil copied and posted a figure on his website under the page name of "EHWave.jpg". This figure was referenced as an extract from a book by Haznadar and Stih entitled "Electronic Fields, Waves, and Numerical Methods."

The figure itself completely misses the point, since it is simply a representation of an ordinary circularly polarized wave. The topic of polarization is not particularly relevant here. It merely complicates the arithmetic, and it adds nothing to the science of Poynting vectors or standing waves. It is, however, interesting to note that the figure caption in the original source is given quite clearly. On page 241, the page containing Cecil's copied jpeg, it says,

"Figure 8.3.2 Propagation of a circularly polarized pure direct (in the +z direction) travelling wave with phase velocity vf = c."

Whether Cecil did not see this caption, did not understand it, or was again trying to pull a fast one remains unknown. It matters not in any case.

I must give great credit to Cecil's hidden research team for finding this reference. It seems quite obscure. However, Cecil's groupies appear to have neglected to turn a few pages to arrive at page 244. On this page there is a discussion of the Poynting vector for standing waves. An exact quote, or at least as close as possible in ASCII, is,

****

"In a real domain, the instantaneous value of Poynting's vector for a pure standing wave is, according to (8.3.26a,b),

NRe = (ax ExRe x ay HyRe) = -az 1/4 (Eo^2)/Z' sin^2 (2 pi z/lambda) sin (2wt) (8.3.28b)

Using this expression, we see that the time-averaged value of Poynting's vector in a real domain is equal to zero since the time-averaged value of the function sin (2wt) is always equal to zero."

****

The equation is slightly cleaner when the "Re" subscripts are removed.

N = (ax Ex X ay Hy) = -az 1/4 (Eo^2)/Z' sin^2 (2 pi z/lambda) sin (2wt) (8.3.28b)

What is immediately observed is that the Poynting vector for an ordinary standing wave is zero only for specific locations or for specific times. At other locations and times the Poynting vector is non-zero. Only the time or space *average* is zero. This is of course exactly what I and some others have been saying. This is exactly what the traditional science says. The colloquial expression is that the energy sloshes back and forth.

This equation is easily derived from the standard representation of a standing wave, but it is *so* much more authoritative when Xeroxed from Cecil's own reference book.

The iconoclasts never give up. The 200 mpg carburetor lives on.

73,
Gene
W4SZ

> case.

If I was trying to pull a fast one, I wouldn't have
posted the reference along with the graphic.

The phasors associated with a traveling wave rotate in
opposite directions for forward and reflected traveling
waves, i.e. in their exponential notations, they are
indeed polarized. If the forward and reflected waves
didn't rotate in opposite directions, the standing
waves wouldn't stand. That graph is a reasonable graph
of a uniform plane wave in exponential notation.

My graph of the superposition of forward wave phasors
and reflected wave phasors still stands at:

http://www.w5dxp.com/EHSuper.JPG

The Re part of those phasors (the fields) are 180 degrees
out of phase.

Quoting "Optics" by Hecht, concerning a traveling wave:
"... a phasor rotating counterclockwise at a rate omega
is equivalent to a wave traveling to the left (decreasing x),
and similarly, one rotating clockwise corresponds to a wave
traveling to the right (increasing x)."

The graphic I posted is a reasonable representation of
a traveling wave illustrated in exponential form. The
fields of a circularly polarized waves are virtually
identical to the phasors of a uniform plane traveling
wave. You can observe the rotation of a traveling wave
by downloading http://www.w5dxp.com/rhombicT.EZ and
turning on the current phase option.

> What is immediately observed is that the Poynting vector for an ordinary
> standing wave is zero only for specific locations or for specific times.
> At other locations and times the Poynting vector is non-zero. Only the
> time or space *average* is zero.

Which is exactly what I have been saying. The instantaneous
Poynting vector is of limited usefulness. The time-averaged
Poynting vector is the one that is useful and the one I have
been talking about, as I stated a couple of times previously.
Every time I have used the words, "Poynting vector", I have
been referring to the average Poynting vector. As you know,
I have been using the word "net" as in, "there is no net energy
flow in a standing wave".

We both agree that in a traveling wave the voltage and
current are in phase for forward waves and 180 degrees
out of phase for reflected waves. The E-field and H-field
are 90 degrees apart in both traveling wave cases. A
traveling wave is an example of a uniform plane wave.

The technical fact that the voltage and current in a pure
standing wave are 90 degrees out of phase proves that the
standing wave is NOT a uniform plane wave. In fact, in an
earlier posting, a standing wave failed all 7 properties
of a uniform plane wave.

V*I*cos(A) = average Poynting vector = 0 for a standing wave.

----

Edmund Laport's RADIO ANTENNA ENGINERING has a good treatment of open wire lines, including a chart on page 398 showing the Zo of balanced, two-conductor line as functions of wire OD and c-c spacing. The text says the plot includes proximity effect and non-uniform peripheral charge distribution. The chart shows a proximity effect only for low ratios of conductor spacing/OD (below about 4). I could scan it and send it to you if you wish.

Laport also shows the general equation as:

Zo = 276 log [2*h*a / p*SQRT(4*h^2 +a^2)]

where

h = height above ground
a =spatial dimension in the line cross-section
p = wire radius

Reg Edwards' "LINE_ZIN" program includes a term for proximity effect.
It happens to be one of the programs for which he provided Pascal
source code. There are a couple lines of interest:

```
Rc:=2*Sqrt(Freq)*Len/12/Dia; { conductor
resistance }
Rc:=Rc/Sqrt(1-Sqr(Dia/Space)*(1-Sqrt(SD/Dia))); { corrected for
proximity }
```

I'd suggest you look up the source code yourself, though, and make
sure that taking these two lines out of context doesn't destroy their
meaning. The above two lines are taken from the archive at
http://www.zerobeat.net/G4FGQ/

There's what seems to me to be a pretty nice qualitative explanation
of proximity effect at http://www.sigcon.com/Pubs/news/4_1.htm. I
realize that's not what you asked about, but lurkers may be interested
in it.

Cheers,
Tom

On the contrary, I've measured some of the Caddock resistors similar to those and they're quite useful to 2 meters and beyond. We were using a 100-ohm 25 watt one in a Wilkinson combiner at 450MHz successfully. YMMV, and as I wrote in this thread before, it does help to have a reliable analyzer to test them with. Much more useful, IMO, than a lot of the drivel that goes on here would be info on ways to bootstrap yourself into some decent measurements. It can be done with very inexpensive home-brew equipment, but it takes some thought and careful construction.

Cheers,
Tom

Hi Tom,

Did you put the MP9100 against a heat sink? The large surface area,
thin construction for heat flow, bound on both sides by metal
clamping, a high dielectric constant, all point to a considerable
sized capacitor (I visualized a 0.01ï¿½Fd ceramic cap).

Also, though it covers proximity effect with relation to coils and not
transmission lines, the article at http://www.g3ynh.info/zdocs/comps/part_1.html
may be of interest. He provides a reference or two, though I'm pretty
sure the references will talk exclusively about proximity effect in
coils, too.

Source record: 28957

Skin effect can, of course, be easily calculated if the conductor diameter is at least several skin depths. If you can't make that assumption, the calculation is much more involved, but not difficult for a computer, involving modified Bessel functions.

There's a graph of a proximity effect factor in Johnson & Graham, _High-Speed Signal Propagation: Advanced Black Magic_, p. 43. The caption says it's derived from Terman's _Radio Engineer's Handbook_ (1943), p. 43. An approximate equation for calculating proximity effect appears on p. 8-51 of Kaiser, _Electromagnetic Compatibility Handbook_ (CRC Press, 2005). It's a bit involved to try and duplicate in ASCII.

Then it is not fully efficient as a diamagnetic material.
You will note that the SS retains energy in its magnetic
condition via a hysteresis curve.

This all got me wondering ...

Just walked out to garage, with a neodymium magnet, where I have some 8+ ft whips stuck up overhead. Only one of them had NO attraction to the magnet at all. I believe it is an old antenna specialists ChickenBand whip!

Apparently, back in the 70's the SS in the whips was better. However, I think the military ones contain the iron for strength, they are tough.

Let me qualify my remarks a bit more. Diamagnetic materials produce an
oxide on its surface
which controls the magnetic field but without retention of energy.
Stainless steel has chromium and nickel as part of its contents which
also produce an oxide on its surfaces. I would imagine that the
configuration of the magnetic field would be somewhat different and
the iron content would also retain magnetic energy instead of using it
for radiation.

Surely you don't think they use high-K ceramic for their substrate.
Assuming alumina, A8 grade if you wish, the thermal conductivity is
sufficient, I believe, to allow a 2mm thick piece 13mm square to serve
the MP9100 at better than the data sheet thermal performance.
Relative permittivity of that alumina is about 10 at most. Even if
the 13mm square were silvered both sides, it represents a whopping
7.5pF. Assuming that's distributed evenly across the resistive
element, it gives you better than 20dB return loss out to beyond
800MHz. For a ham dummy load, that's generally fine. I'll bet this
simple back-of-the-envelope calculation yields a worse result than
you'd see in practice with an MP9100. Please note that I didn't say I
either had, or have used, an MP9100. It was a 25-watt part in a
TO-220 style package from Caddock, and I believe it was a precursor of
the series with exposed ceramic backs. It was about 20 years ago; I'd
have a hard time finding the data at this point. Please feel free to
get one of the MP9100s and measure it yourself. I'm confident the

capacitance won't be anything like 0.01uF.

Cheers,
Tom

Roy, Tom, Richard and Richard,

Thanks.

I only asked half the question, I was also interested in a proximity corrected calc for Zo.

The chart in Laport looks useful Richard. I have digitised it and tried a number of curve fits. I think I will just use a cubic spline interpolation to my digitised points where D/d<2.5 and >1.1, and above that range I will use 120acosh(D/d). Laport doesn't give an expression from the graph, so I suspect that it is derived from experimental data.

Tom, thanks for the pointer to Reg's expression. I wish I knew where he got it from, or something against which to validate it... but it is a start. Interestingly, Reg doesn't seem to consider proximity effect in calculating Zo (other than indirectly from the implied R element).

Roy, I note from Googling that a lot of work has been done in recent years on skin effect in PCB tracks, ie small rectangular tracks over a large ground plane, but haven't seen work on traditional two wire open line.

I am playing with a model of a Ruthroff 1:4 balun. My model treats the windings as a coiled lossy transmission line, so good estimation of Zo and R are important to the results.

The ugly part of ferrite baluns is the ferrite. I have used published u' and u'' vs frequency curves to calculate the choke impedance for a more realistic estimate.

Comments appreciated.

Again, thanks to all for the hints.

Owen

Art wrote:
"So you reject the magnetic field shape of a diamagnetic material as being different from its steel counterpart?"

Yes. A galvanized tower might just as well be solid zinc due to skin effect. No one makes any allowance for zinc, steel, copper, or gold except for resistivity. For that, the adjustment is small indeed.

Further, Maxwell`s equations are ample for all electrical radiation predictions even though these were made before radio waves had been discovered. No addenda are needed.

Best regards, Richard Harrison, KB5WZI

I wonder if Roy's fingers got ahead of his thoughts...at least in My copy of the '43 edition of Terman's book, it's more like page 36. He publishes a graph there of the correction factor for resistance of wires in a two-wire transmission line, for the wires carrying current in opposite or in the same direction. The factor becomes large when the center-center spacing is, say less than twice the conductor diameter, as it would be in twisted-pair for most types of insulating layers.

Terman gives more references. This stuff was all worked out long ago, as I'm sure Reg would tell us if he were around. OK, quoting the footnotes in Terman:

With respect to the calcs that went nto his published curves, which assume skin depth small compared with other dimensions involved,

"1. The curve for currents in opposite direction is calculated by formulas given by Sallie Pero Mead, Wave Propagation over Parallel Tubular Conductors: The Alternating Current Resistance, _Bell_System_Tech._Jour.,_ Vol 4, P. 327,1 April, 1925. The curve applying to currents flowing in the same direction is from S. Butterworth, On the Alternatng Current Resistance of Solenoidal Coils, _Proc._Roy._Soc._ (London), Vol. 107A, p 693, 1925."

With respect to calculating the effect when skin depth is not
negligible compared with the other dimensions involved,

"2. See Mead, op.cit.; also, H. B. Dwight, Proximity Effect in Wires
and Thin Tubes, _Trans._A.I.E.E.,_ Vol. 42, p. 850, 1923."

OK, Owen, if you can actually find these references, it seems like
they should do the trick for you with respect to resistance, at
least. If they also cover the effect on inductance, perhaps they'll
take care of the problem for you. I do have an explanation in a text
about how inductance varies with frequency because of the skin effect,
thereby affecting the impedance of a transmission line, but I don't
believe it covers proximity effect...

Cheers, Tom

Neither do I.

I'd imagine a pulley in the tree which a rope attached to the antenna to be tensioned was attached. This rope would then run to a weight on the ground to where the HD door closers were attached.

I mean, I'd imagine that as opposed to beginning to pour concrete to which an eyebolt with a insufficient deadman held into the concrete!

Thanks Tom,

I did mean to note in my last post that Laport's graph of D/r vs Zo with proximity correction is frequency independent.

I thought the effect would be frequency dependent. Perhaps not sufficient to be concerned about, perhaps he overlooked it?

I did ask Reg about the R calc a long time ago, and he dismissed the discussion with an explanation that it was from notes in his engineering notebook from a long time ago, and then went on the tell me the value of his book of personal 'recipes', but he didn't share it.

When he did publish the source of a few of his progs, it didn't occur to me to look at them for possibly useful hints.

I think the model I have now is probably adequately accurate to question some of the golden rules of baluns. At the end of the day, the uncertainty in characterising ferrites at a frequency, at a temperature, at a flux level, and on a given day is the main worry. I don't think I need to get into Bessel functions for the actual current distribution, and trying to derive corrected values for R and Zo from first principles.

Try to keep your anonymous sniping to yourself, CB "John". There's *no*
dead man in the concrete. It is simply a bolt, a large fender washer
and a nut. It is supporting only a wire antenna. It isn't guying a
tower. A 3/8", three or four inch long bolt in concrete is more than
sufficient for the job. Read my earlier post where I suggest a window
sash weight. These are cast iron with a loop at the top end. Both have
been used without failure for decades. No Rube Goldberg devices were
necessary.

It is interesting that you bring all this up just at this time. The
past couple of days, I've been playing with making a balun out of a
twisted-pair transmission line. One of my big problems right now is
making a decent 50 ohm twisted pair (or I was thinking of making a
twisted four-wire line, but it's kind of painful trying to keep the
wires in the same order all the way along the line -- this with Litz
wire (15 strands of 44AWG)...). Tomorrow I'll probably try a twisted
pair of 32AWG polyurethane magnet wire. I believe it will come out
reasonably close to 50 ohms. I'm interested in doing this with no
magnetic core, as such a core introduces distortion, and I really want
to avoid that.

Cheers,
Tom

For the record, I have not used field vectors at all during this discussion. Everything I have ever posted have used phasors. From the IEEE Dictionary, "E and H are the electric and magnetic field vectors in phasor notation". That is what I have been doing all along.

From "Optics" by Hecht: "Therefore, its instantaneous value [for the Poynting vector] would be an impractical quantity to measure directly. This suggests that we employ an averaging procedure." Virtually every time I have used the term, "Poynting vector", I have been talking about the average value, not the instantaneous value.

EHWave.JPG is a good representation of an EM traveling wave in phasor notation. If we project the fields onto the real axis, we obtain the conventional representation.

Check it out, "John". The fender washer was in my original post. If
you'd bothered to read it, you wouldn't be in an "Oops, never mind"
situation.

The "notation" is not the most important part. "Phasor notation" is simply a means expressing the phase in terms of complex numbers. The vector *direction* is all-important. That is the essential "vector" part of the Poynting analysis. The vector *direction* is not addressed at all by the phase or by phasor notation. Depending on the exact notation, the vector "magnitude" may be described by phasor notation. If one is going to correctly perform Poynting analysis, it is necessary to consider field vectors. There is no alternative.

Most of this discussion has been based upon a disagreement between your insistence that the instantaneous Poynting vector for a standing wave is always zero at all times and places, compared to my insistence that it is not zero at all times and places. I have no disagreement with Hecht.

>

The representation in EHWave.jpg is already shown in real axes. There is no projection needed. The whole point of that figure is to show a circularly polarized wave. The vector direction does indeed rotate around the propagation axis exactly as shown. The observed rotation angles around the propagation axis have nothing to do with phasors; they are real physical angles of the E-field and H-field.

>Regards. Bob

Hi Bob,

There is every probability that either of your links will work,
although I still have a sample request that remains to be filled (but
I am in contact with their engineers).

However, backing up to the actual application, this is still not a
done deal if you are trying to push them to their "ratings." The
larger part of success is in the details, and for Heat Transfer, that
is a devil.

The practical solution will require a sink with fins and forced air in
ambient to still find it derated by 60%. Ham applications rarely
subject a dummy load to full power continuously, however. So, a good
heat sink and a one minute application of full rating in ten minutes
"may" be tolerated. You can always water cool them.

You apparently did not bother to read the IEEE Dictionary
definition above. Please do it and while you are at it,
would you please explain what the "complex conjugate"
means when one is not dealing with phasors? Exactly what
is the complex conjugate of a vector in free x,y,z space?
For instance, what is the complex conjugate of a vector
running from 0,0,0 to 1,2,3?

Either I misspoke or else you misunderstood. Phasor
magnitudes are usually RMS values, i.e. average
values.

If I ever said anything about the instantaneous Poynting
vector, it was a mistake. Every time I said "Poynting
vector", I was referring to the average Poynting vector.

I tend to agree with Hecht - the instantaneous Poynting vector is impractical to work with.

I always deal with phasors and averages. When I realized that Keith was talking about instantaneous values, I backed out of the discussion. I do not agree or disagree with anyone about instantaneous values. I just think they are of very limited usefulness in this discussion. It is the average values that are important here.

So I repeat: The average energy flow in a standing wave is zero so the average Poynting vector for a standing wave is zero. That was the only point I was trying to make. V*I*cos(A) are RMS phasors.

A suggestion. Read the IEEE Dictionary definition of "phasor" and report
back to us if you think it is used to specify a direction in real space
rather than phase space in the complex plane.

Yes, the complex conjugate adjusts the phase portion of the wave
description. However, it does not impact the real-space vector direction.

I know the difference between phasors and vectors, Gene.
Most of my textbooks represent the E and H fields as
phasors, rather than vectors, by applying some logical
boundary conditions to the vectors. The IEEE Dictionary
says the E and H fields are represented as phasors.
You seem to stand completely alone in your insistence
that E and H fields cannot be represented as phasors.
Would you mind providing one iota of proof for that
assertion?

> Yes, the complex conjugate adjusts the phase portion of the wave
> description. However, it does not impact the real-space vector direction.

Contrary to *all* of my references, you said the Poynting
vector equals E x H* which apparently implies phasors rather
than vectors. Would you care to explain your H* notation
as it applies to real-space vectors? This is my question
which you didn't answer - asked in different words.

Exactly what is the complex conjugate of the vector that
extends from 0,0,0 to 1,2,3?

No, actually it comes from the notion that where there are no
electromagnetic waves there is no electromagnetic energy, and vice versa.

> Antennas radiate equally in all directions from all points. Nulls are
> the products of the sums of those radiations at a remote point.

A point which blossoms into the notion that antennas radiate
nonexistent waves carrying nonexistent quantities of energy in certain
directions.

But that's in the wrong direction, Cecil. You claim there's power in the canceled waves. You need to be able to measure that for the proof of your belief. Obviously there's energy in the forward waves. They're not canceled.

Your attempt at obfuscation is well known to all, Jim.
Two canceled waves cease to exist but the energy in the
two waves that canceled cannot cease to exist. I'm
surprised that a physics professor would be advocating
violation of the conservation of energy principle.

Maybe you would like to contact the scientist who
answered the question at:

http://www.newton.dep.anl.gov/askasci/phy00/phy00292.htm

Perhaps he can explain the laws of physics to you.

"The waves' energies simply add together. In places where
the interference is destructive, one wave cancels out the
other. (up + down = nothing.) Where it is constructive,
however, they reinforce each other
(up + up = 2 * up, down + down = 2 * down.)
That is all there is to it."

It is your propensity for baseless accusation that is well known
around here, Cecil.

> Two canceled waves cease to exist but the energy in the
> two waves that canceled cannot cease to exist.

I'm sorry you're having so much trouble understanding such a simple
idea. It really does turn you surly. The waves don't 'stop
existing'. Given the conditions, they can never exist. In the steady
state, things don't first do one thing, and then some time later do
something else.

Source record: 28996

Jim Kelley wrote:
> You claim there's power in the canceled waves.

That is a false statement and you are either totally
confused or bearing your usual false witness.
I have never claimed that there is power in the
canceled waves *after* they cancel, only that there
was energy in them *before* cancellation took place.
The HP ApNote 95-1 on s-parameters agrees with me.

b1 = s11*a1 + s12*a2 now square both sides

|b1|^2 is the reflected power
|s11|^2 is the power reflection coefficient
|a1|^2 is the forward power
|s12|^2 is the power transmission coefficient
|a2|^2 is the reflected power

It's obvious that you don't understand the HP
ApNote.

There's zero energy in the total superposed wave
after cancellation. There was energy in the two
waves before they were superposed. That energy
cannot be destroyed no matter how loudly you complain.
It is more than apparent that you detest the conservation
of energy principle because it works against your
argument. But as they say in Russia, tough shitsky.

When two waves are canceled, their energy components
are redistributed to another area. In a transmission
line, with only two directions possible, their energy
components are redistributed in the other direction
from their original direction of flow. What is it about
the Melles Groit and FSU web pages that you don't
understand and what is it about the following that you
don't understand?

"The waves' energies simply add together. In places where
the interference is destructive, one wave cancels out the
other. (up + down = nothing.) Where it is constructive,
however, they reinforce each other
(up + up = 2 * up, down + down = 2 * down.)
That is all there is to it."

Richard E. Barrans Jr., Ph.D.
Assistant Director

PG Research Foundation, Darien, Illinois

P3 + P4 - 2*SQRT(P3*P4) = 0 = nothing
P1 + P2 + 2*SQRT(P1*P2) = 2P1 + 2P2
That is all there is to it.

>
> I'm sorry you're having so much trouble understanding such a simple
> idea.

The idea that canceled reflections never existed in the
first place is not a simple one. If they never existed
in the first place, there is no reason to ever try to cancel
them because there was never anything to cancel. In effect,
you are saying the lack of reflections causes the reflections
never to have existed. Not only is that confusing cause and
effect but it also introduces time travel. "If you went back
in time and killed your grandfather before you were born,
you would cease to exist." But if you never existed, who
killed your grandfather? That's the exact logic that you
are using.

> It really does turn you surly. The waves don't 'stop existing'.

Yes, they do. They stop existing in their original direction
of travel. A reflected power meter proves it. A forward power
meter proves that the energy that existed in the canceled
waves joined the forward wave. What is it about the Melles-
Groit and FSU redistribution of energy explainations that
you don't understand?

> Given the conditions, they can never exist.

If reflections never exist, there is no need for a non-
reflective coating, is there? People who buy non-reflective
picture frames are wasting their money since the reflections
never exist. What is it about the Melles-Groit and FSU
explainations about redistribution of energy from the
canceled waves that you don't understand?

> In the steady state, things
> don't first do one thing, and then some time later do something else.

I've explained this before. Wave cancellation is a continuous
steady-state process. Ptot = P1 + P2 - 2*SQRT(P1*P2) = 0
is a continuous process. Every dt, waves P1 and P2 are
in the process of canceling each other during steady-state.

I have a home brew dipole antenna made from #22 copper What is ther
maximum power
that it can handle. Support is not a problem. I want to test it for
max power using a 8877 which will blow if the wire
opens, and they are costly. Ofcourse I would like a bit of safety in
hand. Does minimum wire size vary much dependent on band useage? I
have no idea what manufactures use for commercial style antennas!

If it is a 1/2WL dipole, the current will be maximum
at the feedpoint. Will #22 wire handle your current
at the feedpoint? Skin depth is frequency dependent.

Just a joke Dave. Read the "A pencil through the eye will hold it
in position until the concrete cures" out of it's proper context.

Hey, I didn't say it was all that good of a joke.... ;^)

But that's in the wrong direction, Cecil. You claim there's energy in the canceled waves. You need to be able to measure that for the proof of your belief. Obviously there's energy in the forward waves. They're not canceled.

I certainly do *NOT* claim there's energy in the
canceled waves after they are canceled. If you could
win the argument without bearing false witness, you
would already have done so.

You seem to be acting obtuse just for the hell of it.
There is energy in the canceled waves before they are
canceled. It's equal to 2*ExB. After they are canceled,
that 2*ExB energy heads in the opposite direction toward
the load. Consider that the following s-parameter
equation is a steady-state process.

b1 = s11*a1 + s12*a2 = 0

This is a continuous steady-state process. There is
energy in s11*a1. The power is equal to |s11*a1|^2
because s11 and a1 are not zero. There is energy in
s12*a2. The power is equal to |s12*a2|^2 because s12
and a2 are not zero. The power in b1 is equal to |b1|^2.

|s11*a1|^2 + |s12*a2|^2 - destructive interference = 0

For instance,

|s11*a1|^2 = 100 watts, |s12*a2| = 100 watts

Is that calculation beyond your math capabilities?

100w + 100w + 2*SQRT(100w*100w) = 0

There is a total of 200 watts in the two waves just
before they cancel during steady-state. Those 200 watts
head back toward the load after they cancel. That is
NOT a one time occurrence. It is a continuous steady-
state occurrence. The two waves are being continuously
canceled during a steady-state wave cancellation process.

Please read the HP ApNote 95-1 until you understand it.
Please study the irradiance equation until you understand
that it is a steady-state process.

Richard Clark wrote:
"Perhaps others will join in."

Haven`t read all the postings and don`t propose to contradict anyone. Radio waves are energy in motion. They continue so long as their supply does.

The same energy can`t be in two places at once. Energy can be redirected. Practical antennas are an example. The only non-directional antenna is the imaginary isotropic radiator which if it were constructed would by definition produce waves of equal strength in all directions. Terman says on page 871 of his 1955 opus:
"Thus a gain of 4 (or 6dB) means that the power intensity is 4 times as great (field intensity twice as great) as would be the case if the radiator in question were an isotropic antenna radiating the same total power."

The foregoing tells us power phased-out in some directions is redirected to a direction of maximum radiation. Constructive interference exactly equals destructive interference because a fixed amount of power is available and conservation of erergy must be satisfied.

The same is true on a transmission line whose only possible directions are forward and reverse.

Best regards, Richard Harrison, KB5WZI

Just cut the BS, Cecil. In order to prove your assertion you must first be able to describe how two co-linear, coherent waves that are 180 degrees out of phase at every point along their path and traveling in the same direction can under those circumstances at any time produce measureable energy. In addition, you must be able to measure it. Let me know when you do.

It is an indirect measurement, Jim. Given the s-parameter equation, b1 = s11*a1 + s12*a2 = 0, s11 is not zero, a1 is not zero, s12 is not zero, and a2 is not zero. Although HP cannot measure those quantities either, they tell us that |s11*a1|^2 is in watts, e.g. 100 watts. They tell us that |s12*a2|^2 is in watts, e.g. 100 watts. When all energy is accounted for, it is obvious that those 200 watts are no longer in the direction of the source but have changed direction toward the load. This ain't rocket science.

If reflections are eliminated toward the source by wave cancellation, the reflected energy is redistributed back toward the load just as explained on the Melles-Groit and FSU web pages. If it weren't headed for the source in the first place, they wouldn't say it was "REDISTRIBUTED". If 200 joules/sec disappear toward the source and there are only two directions in a transmission line, do you really want to tell us that you can't figure out in which direction those joules go? Do you need help from my 10 year old grandson?

You clearly fail to understand the process defined by the wave reflection distributed network model. Until you are in a position to discredit that model, you are just blowing smoke.

Since I never said anything resembling that, you are
just up to your old semantic tricks, well known to
this newsgroup. If you still lack a conceptual grasp
of the process, please avail yourself of the flash
demo at:

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

Set the two waves to equal magnitudes and opposite phases.
Hint: there can be no wave cancellation without waves.

The point I was trying to make is that the forward power
into a Z0-match point can be 100 watts while the forward
power out of the Z0-match point is 200 watts. In that
case, the Z0-match point is an interferometer of sorts.
An ideal non-reflective thin-film coating on glass is a
Z0-match. Hint: characteristic impedances are directly
related to indexes of refraction.

Good point, Richard. Wf = Wl + Wr. Amidst all this consternation about conserving the energy in canceled waves, we should not lose sight of the fact that it is *reflections* (not canceled waves) which cause forward power to measure greater than power dissipated in the load.

> ac6xg
>

now lets really have some fun with the cancelled wave and disappearing energy crowd that redirects power from here to there and sloshes it back and forth so it doesn't go anywhere.

This is after all an antennas group, so lets take a real antenna. I have 2 160m verticals that are 1/2 wavelength apart over a pretty darn good ground. Now, I can feed them either in phase to get a broadside pattern, or I can feed them 180 degrees out of phase to get an end fire pattern. Everyone here should agree that this works as it has been well demonstrated over the years, and even nec predicts it so art should be happy.

Now you may ask, why is this any big revelation... well, because it is a perfect example of waves that cancel but don't disappear, slosh, or get redirected anywhere. consider the case where the 2 verticals are fed 180 degrees out of phase. on a line 1/2 way in between them and perpendicular to them there is perfect cancellation of the two waves... and yet, you can move just a little bit off this line of symmetry and viola, the waves are both there and add as expected. in fact if you walk from one vertical to the other and keep on going on that line you will come to the center point where the waves perfectly cancel, then keep walking and just 1/4 wave later when you get to the next vertical, and everywhere from there on the two waves add together.

Now how does that happen?? is there some kind of magical reflection field set up so that no power can cross that midpoint line?? maybe this is the first evidence of a star trek type forcefield that magically deflects phasors while still letting you see the photons?? So where does the power go??? at that mid point E=0, H=0, ExH must also be 0 at all time, and

everywhere along that symmetry plane... so how can the waves add up again on the other side? quantum tunneling? art's magical levitating cosmic diamagnetic particles??? virtual photons?? oh, I forgot, these verticals are copper clad steel, doesn't the steel mess them up or something because the cosmic particles fly away? or is the thin copper enough to let them settle on an otherwise insulated slippery vertical surface??

I know what the equations say... I also know what the contest results say... the waves keep going, and going, and going... and the qso's keep coming, and coming, and coming. So lets see how well art's magical mystery antenna plays in the ultimate 160m contest this weekend... how about it art, I'm sure everyone would love to see you prove your little antenna can out play something bigger??

More to the point, there can be no waves under the conditions you describe. So, again, just when do these waves actually exist, Cecil? We apparently agree that it's not when they cancel. The only other possibility I can think of would be when they don't cancel. So, when don't they cancel? Does it occur in steady state?

Now all you have to do is figure out how those reflected
waves reverse their momentum to become forward waves.
You have never offered any explanation for that phenomenon
while criticizing everyone else's explanations.

I don't criticize everyone else's explanations, Cecil. We've discussed this countless times. It's not new or revolutionary, and there are of course pictures of it in physics books that you can look at. Born and Wolf has one, and so does Roller Blum, Physics Volume 2 - as I've pointed out before. You even have a similar chart illustrating it on your web page. Obviously I didn't invent it. It's been right there all along, just as I've told you countless times before, and naturally it (of necessity) blends seamlessly with all of your other favorite quotations.

In considering the transmission line matching transformer scenario (or the antireflection coating), when we sum up all of the partial reflections at each interface during the transient period, the sum ultimately reaches and establishes the steady state conditions. The sum of the reflections at each iteration show exactly how energy makes its way from source to load.

But to follow the energy path correctly we absolutely have to approach the problem either from the standpoint of fields or as voltages. Power doesn't propagate. Fields do - therefore only an analysis from that standpoint avoids pitfalls and misconceptions. If you want to see how energy moves, then power should be calculated after a proper voltage analysis, not in lieu of one. When approached in this manner, it is very simple to see how energy actually does move through the system. Note that you get the same answer in the end either way. Both approaches obviously conserve energy. Scattering parameters and irradiance equations are accurate shortcuts to that end. But one should be careful not to read (or invent) too much physical science into the shortcuts. They're mathematical shortcuts, not phenomenological descriptions of nature.

We're not the only ones arguing about this. I read that 2 lasers pointed at each other 180 degrees out of phase causes darkeness (cancellation). What happens to the energy? I have found no simple answer, yet. We may need to rely on the 'dark physics' for an explanation. Here is a very interesting post on the energy cancellation topic from PhysOrg forum:

"First off, let me thank you for calling my attention to the way I worded my thoughts about phase cancellation, I agree with you about the fact you cannot destroy energy. The point I was attempting to make was that phase cancellation when applied to an electromagnetic wave appears to me to violate the law of the conservation of energy. If an electromagnetic wave does not need a medium to travel through such as was originally thought when the aether was conceived then can we apply phase cancellation the same as we see it in other wave propagations such as waves on water or sound waves? For waves to exist in a body of water (the body of water the medium for which the waves will travel) energy is transferred directly to the water to create the waves and the same holds true for sound waves as well, energy is directly transferred to the medium in which the sound waves will travel which in turn creates the waves. For these two examples phase cancellation happens within the medium itself. For instance, when a sound wave cancels the air in which the wave is traveling has the high and low pressure wave fronts which equalize pressure canceling the waves.

How can this hold true for an electromagnetic wave experiencing phase cancellation which has no medium? My experiments are leading me to the idea that these waves are coupling. Not only that but the coupled waves will exist as a stationary coupled wave. These coupled waves exist more like a particle than a wave, they appear to have the three dimensional x,y and z coordinates associated with particles. Continued coupling appears to be taking place. They appear to develop spin possibly due to electric charge.

These experiments remind me of dark energy and maybe I have found its source. I have to wonder if there really is a medium in which electromagnetic waves travel through."

Therefore, thin-film anti-reflective coatings are
a waste of time since there were no reflections to
begin with. Again, you have an effect reaching back
in time to change its own cause. If that works in
your mind, who am I to try to change it?

Even more interesting is the author's web site. It actually relates much to
what has been discussed thus far in classical terms. You can look for chinks
and I'm sure you will find them but I know his fundamentals are true. This
guy has an intersting vision to say the least:

The reflection model works just fine for the transient state *and* for the steady-state. The principles of superposition tell us that it doesn't matter how the steady-state signals are divided up. Their sum is always the same.

You divide it up into transient reflections. It can just as easily be divided into ten equal parts and the result will be identical.

I can devise an example using two sources with circulators with no reflections where steady-state is immediate. The results are exactly the same as a single source with reflections.

> If you want to see how

Please do a voltage analysis for an anti-reflective coating tuned for laser light and get back to us. Optical physicists have been doing irradiance analysis for centuries, Jim. If you can prove them wrong, have at it. All I am doing is an irradiance analysis inside a transmission line based on centuries old techniques from the field of optics. Since you reject an irradiance analysis, your argument is not with me but with the physicists who invented the irradiance analysis and equation.

Plane waves traveling in opposite directions cause
standing waves. A dark point can certainly result.
But plane waves traveling toward each other cannot cancel.

Only coherent, collinear waves traveling in the same
direction can permanently cancel thus redistributing
the energy in another direction.

Take a look at this interferometer experiment. The
energy reflected back toward the source by wave
cancellation at the standard output is redistributed
to the non-standard output.

Yes, you'll have to look beyond normal science, perhaps deep into the realm of X files and poltergeists, for an explanation of the darkness, since that's not what you get when you point two lasers at each other. Write the simple equation describing the sum of out-of-phase waves moving in opposite directions. You'll find you get a classical standing wave pattern, not "darkness".

Source record: 29039

Let's take a look at the energy in pulses and sine waves. At the end of the day, the energy all has to be accounted for, whether it superposes or not. It's really not all that difficult to do the analysis, as long as we're careful not to fall into the traps which seem to have tripped up quite a few others.

First a rectangular pulse. The energy E it takes to launch a pulse of voltage Vp and duration T (seconds) on a transmission line of characteristic impedance (assumed purely real) Z0 is Pp * T = Vp * Ip * T where

Pp is the constant power applied as the pulse as created
T is the length of time the power was applied
Vp and Ip are the voltage and current of the traveling pulse

The pulse is a traveling wave, so for a forward traveling pulse, Ip = Vp / Z0; consequently, E = Vp^2 * T / Z0 = Ip^2 * T * Z0. Note that it's essential to assume a purely resistive Z0 for this simple time-domain analysis, since a reactive Z0 would cause a distortion of the pulse shape.

Once launched onto the line, we don't have any guarantee that all the energy will stay within the spatial boundaries of the pulse -- all we know for sure is how much total energy we've put into the line. But we can conceptually freeze the pulse at any instant and see where the energy is. Let's do that.

The obvious way to determine the energy in the pulse is to integrate the power, which we can easily calculate. This is, after all, what we did to find the energy we put into the line in the first place. But we're interested in the energy distribution as a function of physical position at an instant of time, so we can't find it by integrating the power. (This is a mistake that seems to be commonly made.) Why not? Well, first of all, energy is the *time* integral of the power. If we integrate the power over a time interval of zero, the result is zero. We could look at a single position on the line and integrate the power during the time it takes for the wave to move by, to get the amount of energy which went by during the time interval. But that's an indirect way of seeing where the energy is on the line at a given time, and can easily lead to invalid results. There are at least two potential problems with integrating the power over a period of time to get the energy which passes a point. The first is that we assign a sign to power, negative when energy is traveling one way and positive when traveling the other. Consequently, the result of the integral can be positive or negative. Although the concept of negative potential energy is a valid one, I don't believe it really applies to this situation, so one would have to be very careful in interpreting and dealing with the sign resulting from the

integration. The second potential problem is that an integral never produces a unique answer, but only an answer that's correct to within a constant which has to be separately determined. Careless evaluation of the constant or ignoring it altogether can produce invalid results.

So what I'm going to do is to evaluate the stored energy *per unit length* of the line at each position along the line. The meaning of this is that if we were to choose some sufficiently short segment length, the amount of energy stored on each segment will be proportional to the energy per unit length evaluated at that segment. In other words, I'll evaluate the energy density as a function of position, or the energy distribution along the line. This tells us where the energy is at the instant of evalulation. I'm going to use the convention that the stored or potential energy of a discharged line (V and I = 0) is zero.

The energy per unit length stored in the electric field, or line capacitance, is C'V^2/2, where C' is the capacitance per unit length and V is the voltage on the segment of line being evaluated. V is assumed to not vary significantly over the segment length. We can let the segment length approach zero as a limit, and say that the energy per unit length is this value at any particular point along the line, where V is the voltage at that point.

Likewise, the energy per unit length stored in the magnetic field, or line inductance, is L'I^2/2 where L' is the inductance per unit length. The total energy stored per unit length at any point is

E' = (C'V^2 + L'I^2)/2

On our line with purely real Z0, Z0 = sqrt(L'/C'), so L' = Z0^2 * C' and

E' = C'(V^2 + (Z0*I)^2)/2

where
E' is the total stored energy per unit length (or energy density) at some point
V is the voltage at that point
I is the current at that point
Z0 is the (purely real) line characteristic impedance
C' is the capacitance per unit length

Length units for E' and C' can be anything as long as they're the same for both.

Now let's look at a traveling pulse. We'll freeze it at some instant while it's traveling down the line.

At any point to the left or right of the pulse, V and I are zero, so the energy density is zero except where the pulse is. Where the pulse is, V is the pulse voltage Vp and I the pulse current Ip, so

E' = C'(Vp^2 + (Z0*Ip)^2)/2

For a traveling wave, I = V/Z0, so

E' = C'Vp^2

This energy density is constant over the whole length of the pulse, since Vp and Ip are constant over that distance. The total energy in the pulse is then

E = E' * len = C'Vp^2 * len where len is the length of the pulse in the same length units as C' and E'.

Because the energy density beyond the pulse in both directions is zero, this is also the total energy in the line, which must equal the amount we put in originally. So

E = C'Vp^2 * len = Vp^2 * T / Z0

from which we can calculate C' = T / (Z0 * len). Some manipulation of this gives

T / len = sqrt(L'C') which relates line delay to L' and C', a result which can be derived by other means.

All the energy in the line is accounted for -- it's traveling along with the pulse, confined to the width of the pulse as we'd expect.

Ok, now let's fire another pulse at it from the other end of the line, and see what happens when they completely overlap. Call the pulse 1 and 2 voltages Vp1 and Vp2, and currents Ip1 and Ip2. Assume that both have the same duration T and therefore the same length len.

Voltages and currents (or E and H fields) add in the overlap region, so the total V and I are the sum of the individual pulses' V and I. The energy density in the overlap region is then:

E' = C'((Vp1 + Vp2)^2 + (Z0*(Ip1 + Ip2))^2)/2 * len

= C'(Vp1^2 + Vp2^2 + 2*Vp1*Vp2 + Z0(Ip1^2 + Ip2^2 + 2*Ip1*Ip2))/2

But what's the simple sum of the energy densities of the two pulses?

E1' + E2' = C'(Vp1^2 + Vp2^2 + Z0*(Ip1^2 + Ip2^2))/2

Oops! The energy density of the sum of the two pulses isn't the same as the sum of the energy densities of the two pulses! And Since the overlap region length is the same as the single pulse length, the same holds true for the total energy. The problem is the two additional terms in the total energy density 2*Vp1*Vp2 and 2*Z0*Ip1*Ip2.

It turns out that we're saved -- For the forward traveling pulse, Ip1 = Vp1/Z0. For the reverse traveling pulse, Ip2 = -Vp2/Z0. So when the appropriate substitutions are made, we find that 2*Vp1*Vp2 + 2*Z0*Ip1*Ip2 = 0, so the energy in the sum of the pulses is equal to the sum of the energies of the pulses. And this is true regardless of the values of Vp1, Vp2, Ip1, and Ip2. That is, it's true for any two pulses, for any overlap length. _Provided they're traveling in opposite directions._

What happens when one pulse is the inverse of the other, that is, one is positive and the other negative? Don't they cancel?

No, they don't. In the overlap region, the voltage is indeed zero. But the current is twice that of each original pulse. The energy is simply all stored in the magnetic field (line inductance) during the overlap. The above equations still hold.

Well, we ducked that bullet. But what if the two pulses are traveling in the same direction? What then? The two troublesome terms don't cancel, so some energy ends up getting created or destroyed. But before worrying too much about that, try to imagine how you'd accomplish it. The propagation speed is the same for all pulses, so there' no way one can catch up with another if both are fired from the input. I believe you can contrive a situation where two pulses can be generated, one from each end which, if long enough, will partially overlap when going the same direction, after reflection. But the overlap and energy calculations will be different than for this example, and I'm sure the energy of the summed pulses will equal the total energy in the line. I'd appreciate seeing an analysis from anyone who thinks he can show differently. Remember that this analysis assumed that no other pulse was present at the input while the pulse was being generated. If one is, the amount of energy going into the pulse will be different. It also assumed a constant line Z0 and velocity factor (constant L' and C'), so a different analysis would have to be used if that condition is violated.

The conclusion I reach is that yes, a specific amount of energy accompanies a pulse on a transmission line having purely real Z0, and is confined to the pulse width. Although it can swap between E and H fields, the energy in the confines of the pulse stays constant in value, and simply adding when pulses overlap.

Sine waves are another problem -- there, we can easily have overlapping waves traveling in the same direction, so we'll run into trouble if we're not careful. I haven't worked the problem yet, but when I do, the energy will all be accounted for. Either the energy ends up spread out beyond the overlap region, or the energy lost during reflections will account for the apparent energy difference between the sum of the energies and the energy of the sum. You can count on it!

As always, I appreciate any corrections to either the methodology or the calculations.

This is simply not true for coherent, collinear waves traveling
in the same direction. "Optics", by Hecht has an entire chapter
on "Interference". He says: "Briefly then, interference
corresponds to the interaction of two or more lightwaves yielding
a resultant irradiance that deviates from the sum of the component
irradiances." Irradiance is the power density of a lightwave, i.e.
watts per unit-area. Paraphrasing Hecht: Interference corresponds
to the interaction of two RF waves in a transmission line yielding
a resultant total power that deviates from the sum of the component
powers. If the total power is less than the sum of the component
powers, destructive interference has taken place (normally toward
the source). If the total power is greater than the sum of the
component powers, constructive interference has taken place
(normally toward the load). It is the goal of amateur radio
operators to cause *total destructive interference* toward the
source and *total constructive interference* toward the antenna.
These terms are defined in "Optics", by Hecht, 4th edition on
page 388. Quoting Hecht:

"In the case of *total constructive interference*, the phase
difference between the two waves is an integer multiple of
2*pi and the disturbances are in-phase."

When the phase angle is an odd multiple of of pi, "it is
referred to as *total destructive interference*.

If anyone works out the phase angles between the voltages, one
will discover that they match Hecht's definitions above.

Every text on EM wave interference that you can find will explain
how the bright interference rings are four times the intensity of
the dark interference rings so the average intensity is two times
the intensity of each equal-magnitude wave. Of course, that outcome
honors the conservation of energy principle. Using 'P' for power
density, the equation that governs such interference phenomena
in EM waves is:

Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(A)

where 'A' is the angle between the two electric fields. Every
textbook on optical physics contains that irradiance equation.
If Ptot is ever zero while P1 and P2 are not zero, one can be
absolutely certain that the "lost" energy has headed in the
opposite direction in a transmission line because there is
no other possibility. Energy is *never* lost.

RF waves in a transmission line obey the same laws of physics as
do light waves in free space. Coherent, collinear waves traveling
in the same direction do indeed interfere with each other.
Sometimes the interference is permanent as it is at an ideal
1/4WL anti-reflective thin-film coating on glass.

> Sine waves are another problem -- there, we can easily have overlapping

There is no problem. Optical physicists figured it out long
before any of us were born.

www.mellesgriot.com/products/optics/oc_2_1.htm

"If the two [out-of-phase] reflections are of equal amplitude,
then this amplitude (and hence intensity) minimum will be
zero."

This applies to reflections toward the source at a Z0-match
in a transmission line.

"... the principle of
conservation of energy indicates all 'lost' reflected intensity

[in the reflected waves] will appear as enhanced intensity in
the transmitted [forward wave] beam."

i.e. All the energy seemingly "lost" during the cancellation
of reflected waves toward the source at a Z0-match in a
transmission line, is recovered in the forward wave toward
the load.

That is exactly what happens when we match our systems. We
cause destructive interference toward the source in order
to eliminate reflections toward the source. The "lost"
energy joins the forward wave toward the load making the
forward power greater than the source power.

I certainly misspoke there. The bright interference rings
are four times the intensity of one of the two equal
waves. The dark interference rings are, of course,
zero intensity.

If the intensity of one wave is P, the intensity of the
bright rings will be 4P and the intensity of the dark
rings will be zero. The average intensity will, of course,
be 2P, the sum of the two wave intensities.

Let's return to the graphic that we earlier discussed.

http://www.w5dxp.com/thinfilm.GIF

When the first internal reflection (0.009801 watts)
arrives at t3 and first interferes with the external
reflection of 0.01 watts), what is the total reflected
power toward the load? What mechanism caused that
unexpected result?

Feel free to use voltages if you like. :-)

An example from optics will make the situation clear.

http://www.w5dxp.com/thinfilm.GIF

At t3, when the 0.009801 watt internal reflection arrives
to interfere with the 0.01 watt external reflection, what
is the resulting reflected power toward the source?

Anyone who can answer that simple question from the field
of optics will understand what happens to the energy in
a transmission line.

Hint: the reflected power is *not* 0.01w - 0.009801w.

This is a distinction with no technical value. Waves in the same location are subject to the usual rules of linear superposition of the fields. Whether you want to call this "interference" is simply a philosophical choice. There is a whole gamut of results resulting from the superposition, ranging from zero field to a maximum of all the field magnitudes combined. The terms "destructive" and "constructive" are sometimes used to denote the extreme cases, but those terms are not so well defined for the more intermediate cases.

There is utterly no scientific distinction that applies to "signals traveling in opposite directions." The mathematical results may look special in the opposite direction case, but the same basic equations apply in all cases.

On Jan 23, 8:35 am, Cecil Moore <nos...@w5dxp.com> wrote:
> Yes, signals traveling in opposite directions don't interfere.
Call this assertion A.

Consider two antennas several wavelengths apart and driven with the same frequency. Exploring the field strength far from the antennas we find regions with zero field strength (nulls) and regions with increased field strength. This variation in field strength is usually ascribed to interference and the pattern of variation is often called an interference pattern.

Similar results can be observed with light (google "two slit experiment").

Locate one of these nulls far from the antennas and follow it back towards the antennas. Eventually you will be on a line between the two antennas.

From assertion A above, is it your contention that far from the antennas it is "interference" that causes the variation in field strength, but that on the line drawn between the two antennas some other mechanism is responsible?

If so, what is the other mechanism? And does it only work exactly on the line, or does it start working when you get close to the line? How close?

Now I suggest that interference works just as well on the line drawn between the antennas as it does every where else and the conditions along that line are not a special case.

That said, when we look at the two slit experiment, it is generally agreed that the photons are redistributed such that there are no photons in dark regions and more photons in the bright regions.

On the line drawn between the two antennas, there are dark regions and bright regions (the standing wave). By analogy, there are no photons in the dark regions and more in the bright regions. But the photons from the two sources were travelling towards each other. What is the mechanism that redistributes the photons such that there are none in the dark regions? Do the photons stop and not enter the dark region? Or do they turn into 'dark photons' as they transit the dark regions? What are 'dark photons'?

At the risk of being both a dullard and messing up all the fun, does not every destructive interference have to be balanced by a constructive interference, which in turn leads to a condition of "Okey dokey?"

A canceled wave needs a reinforced wave, and then nothing is lost, nothing is gained.

Not so. Here's what Eugene Hecht says: "... optical
interference corresponds to the interaction of two
or more [plane] light waves yielding a resultant
irradiance that deviates from the sum of the component
irradiances."

Superposition can occur with or without interference. If
P1 and P2 are the power densities for two plane waves:

If Ptot = P1 + P2, there is no interference because the
resultant power density does not deviate from the sum of
the component power densities.

If Ptot <> P1 + P2, there exists interference because
the resultant irradiance does deviate from the sum of
the component power densities.

> There is utterly no scientific distinction that applies to "signals
> traveling in opposite directions."

Interference only occurs when coherent, collinear waves
are traveling in the same direction. When they are
traveling in opposite directions, standing waves are
the result. Let's limit our discussion to plane waves.

> The mathematical results may look
> special in the opposite direction case, but the same basic equations
> apply in all cases.

Yes, but boundary conditions apply. The phasors of the plane
waves traveling toward each other are rotating in opposite
directions so interference is impossible. Here is a slide
show about interference which only occurs when the waves are
traveling in the same direction.

Of course not - please don't be ridiculous. If the two
antenna elements were isotropic point sources, on a
line drawn between them, there could be no interference
and there would be only standing waves in free space
along that line assuming no reflections from nearby
objects, etc.

Everywhere else there are components of waves traveling
in the same direction so interference is possible anywhere
except on that line between the point sources. When the
sources are not a point, seems to me, interference could
occur at any and all points in space.

My "assertion A above" was about transmission lines,
an essentially one-dimensional context. Two waves in
a transmission line are either traveling in opposite
directions or in the same direction.

Incidentally, I came across another interesting quote
from one of my college textbooks, "Electrical Communication",
by Albert. "Such a plot of voltage is usually referred to
as a *voltage standing wave* or as a *stationary wave*. Neither
of these terms is particularly descriptive of the phenomenon.
A *plot* of the effective values of voltage ... is *not a wave*
in the usual sense. However, the term "standing wave" is in
wide-spread use." [Emphasis is the author's]

Hi Mike -

One could suggest a number of different possible scenarios in which nothing is lost or gained. But an impossible scenario is one which violates thermodynamic principles. Another might describe phenomena which is not in accord with Maxwell's equations. One should therefore feel comfortable discarding any description which is inconsistent with both thermodynamics and Maxwell's equations.

Why do you attribute such magic to the word "interference"? Do you think that Hecht's "interaction" is any different than superposition?

What if the waves are not quite anti-parallel, say at an angle of 179 degrees? Is interference now possible?

Suppose the waves are only 1 degree from parallel. Does that negate the interference?

Repeating: This is a distinction with no technical value.

> interference, which in turn leads to a condition of "Okey dokey?"

Yep, any destructive interference toward the source is exactly
offset by constructive interference toward the antenna. If one
takes time to calculate the component phasor voltages on both
sides of a Z0-match located away from the source, the constructive
and destructive interference is obvious.

> A canceled wave needs a reinforced wave, and then nothing is lost,
> nothing is gained.

Exactly. The reflected energy that appears to be lost as
destructive interference in the direction of the source
when a Z0-match is achieved, is recovered in the forward
wave as constructive interference energy traveling toward
the antenna.

That's everybody? Walter has in fact worked out the very explanation that you don't seem able to comprehend. It's the same one I pointed to in the physics books, which you also don't seem to be able to fully comprehend.

> Exactly what completely reverses the momentum
> of the reflected wave from the load when the power
> reflection coefficient is only 0.5?

Do you have trouble understanding that reflection changes the direction of the reflected waves? When you work the problem as I suggested - using real reflection coefficients - you'll note that no energy is lost. Your explanation is the one that has trouble working the problem using real reflection coefficients.

OK. So it is your contention that "far from the antennas
it is "interference" that causes the variation in field
strength, but that on the line drawn between the two
antennas some other mechanism is responsible".

But why do you say "Of course not" and then proceed to
paraphrase my statement?

When the mechanism abruptly changes from interference
when off the line to "standing wave" when EXACTLY (how
exact?) on the line, is there any discontinuity in
the observed field strengths?

Gene Fuller wrote:
> Why do you attribute such magic to the word "interference"? Do you think
> that Hecht's "interaction" is any different than superposition?

It is not magic. "Interference" and "superposition" simply
have different definitions.

Interference is a subset of superposition, i.e. interference
cannot occur without superposition but superposition can occur
without interference. This subject is covered in every optics
text that I have ever seen, including Born and Wolf. Given two
waves of equal power densities (irradiances) if the resultant
irradiance is not equal to the sum of the two irradiances, then
interference has occurred.

> What if the waves are not quite anti-parallel, say at an angle of 179
> degrees? Is interference now possible?

Impossible in a transmission line which is the context.
In free space, I would guess that interference is possible
in their common direction of travel.

> Suppose the waves are only 1 degree from parallel. Does that negate the
> interference?

For coherent waves in free space, that would ensure interference
until the beams diverged. It should result in the usual light
and dark interference rings.

> Repeating: This is a distinction with no technical value.

Maybe it would help if you published a video of you waving
your hands as you scream that assertion at the top of your
lungs? :-)

It is unethical to bear false witness about what I said.
What I said was:

On a line drawn between two *isotropic point sources*,
when there are no reflections anywhere around, along
that line, interference is impossible. The only thing
existing along that line would be standing waves.
There is no point along that line where the power
density is not equal to the sum of the two sources,
i.e. there is superposition but no interference along
that line.

If the elements are not point sources, interference
is obviously possible at each and every point. I assume
your example elements are not point sources so what you
claimed was my contention was a false statement. If
you can't win the arguments without making false
statements about what I said, you lose anyway.

Cecil, hopefully you understand that even isotropic radiators near each other and excited on the same frequency with the same amount of power will generate far-field pattern nulls.

Maybe I'm misunderstanding you.

The firmware is upgradeable, they promise to allow you access to any new versions of the SDR software.

The CPU is an intel dual core; Just how much processing power do you need to run a radio? But then, you can cruise the web on this "radio!", run other apps (think EZNEC here), etc.

Also, if you need to control it remotely, you can still do so from another computer via firewire (say put the transceiver in your trunk and run it from a laptop in your passenger compartment), LAN, or WAN--wireless-ly. Indeed, you can control this rig from anywhere in the world using VOIP!

Personally, I thought it time to buy. Will certainly beat anything I can homebrew here ... your mileage may vary.

If you include wave cancellation as a mechanism for
energy reflection, I agree 100%. See the interferometer
example below.

I understand that a physical power reflection coefficient
of 0.5 cannot cause 100% reflection as you say it does.

One wonders why you have not commented on the interferometer
experiment that intercepted the energy reflected from the
standard output during destructive interference and routed
it to the non-standard output thus illustrating an equal
amount of constructive interference.

http://www.teachspin.com/instruments/moderni/experiments.shtml

"Using Dielectric Beamsplitters to find the "missing energy"
in destructive interference - Where is the energy of the light
going in an interferometer adjusted for destructive interference?
Below is a schematic diagram showing a way to detect the non-standard
output of a Michelson interferometerï¿½the light *heading back toward*
the laser source. That is, when interference is destructive at
the standard output, it is constructive at the non-standard output.

If you would just work the problem the hard way, you would see where you're misconception lies. Any given wave front will never reflect 100% from a surface which is only 50% reflective, no matter how vicious your insults become, how may URLs you cut and paste, or how furiously you wave your hands. But when you work the problem as has been suggested you will see how energy gets from source to load. It does not rely on macroscopic layman's explanations or mathematical shortcuts in order to get there.

The only energy "lost" by partial reflection in the process is that which is reflected back toward the source or stored in the system during the transient period. The sum of all the partial reflections equals the energy stored in the system (less the portion of energy admitted to the load or reflected back to the source). After the transient period, no energy is reflected back to the source, and the energy entering the system from the source equals the energy existed the system through the load.

I know that you understand the difference between potential and kinetic energy in mechanics. Please try to consider that the concepts are no less valid in electromagnetism. (Note that we even use the word 'potential' to describe voltage.)

The difference is that your example contained elements
that are not zero dimensions. My assertions covered only
antenna elements of zero dimensions. I repeat:

On a line drawn between two coherent isotropic radiators,
in the absence of any reflections, interference along
that line is impossible because the average total
power density all along that line is constant.
There is no interference in standing waves given
"interference" as defined by Eugene Hecht in "Optics".

That's all you have to say, Jim, to defeat your argument.
If you would stop refusing to perform a simple calculation
involving my example at:

http://www.w5dxp.com/thinfilm.GIF

you would understand. When the internal (0.009801w)
wave reflection arrives at t3 and interferes with the
(0.01w) external reflection wave, what is the resulting
reflected power back toward the source. When you calculate
the results and realize that it is not 0.01 - 0.009801 watts,
you will begin to understand the nature of interference.

It isn't necessary for the radiators to be in each other's far field.

Here is a link to a plot of the far-field elevation pattern of a linear
array of three isotropic sources at one lambda vertical spacing.

Please define "field strength". The total average
power density along a line drawn between the two
point sources is constant, i.e. the average sum
of the energy in the E-field and H-field is
constant. If you are defining "field strength"
as only the E-field, of course standing waves
are the cause, not interference, as defined by
Hecht in "Optics".

Wow!

An 8877 could develop 1.5 to 2kW output power (if done in a part of a world where it's legal for a ham to use that much power.)

2kW into a 50 ohm load is a current of 6 or 7 amps, assuming it's a perfect match/no standing waves.

The fusing current of 22AWG copper wire is about 40 Amps. So if everything is working and matched, it won't melt.

The higher you go in frequency, the more you'll have to derate the above, but for low HF it'll be not too bad.

But geeze.... you've got a multi-kilowatt amp and can't afford anything better than 22AWG wire???

Traditional rule-of-thumb for ham wire antennas would say that if you're pumping more than a kilowatt in, you want at least 12 gauge or 14 gauge wire. There's also the N.E.C. specs, which say that copper antenna wires have to be thicker than 14 gauge up to 150' spans, and thicker than 10 gauge over 150' spans.

Sorry about that. English semantics strikes again. Your
line was indeed "between" the two sources but not the
"from - to" line that I had in mind when I said "between". :-)

I seriously doubt that you are blind to the contradictions
in your argument and are simply hoping to slip them through
while no one is paying attention. Suffice it to say, it is
impossible for a 50% reflective surface to cause 100% reflections
without help from interference in the form of wave cancellation
due to permanent destructive interference. Anybody who understands
the process of anti-reflective thin-film coatings understands
the process of destructive interference redistributing the energy
in the direction that allows for constructive interference.

http://www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and
the thickness of the film are such that a phase difference
exists between reflections of p, then reflected wavefronts
interfere destructively, and overall reflected intensity is
a minimum. If the two reflections are of equal amplitude,
then this amplitude (and hence intensity) minimum will be
zero." (Referring to 1/4 wavelength thin films.)

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity
will appear as enhanced intensity in the transmitted beam.
The sum of the reflected and transmitted beam intensities is
always equal to the incident intensity. This important fact
has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not

actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit
constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

Yep, and that describes your strange concepts to a 'T'.
Your concept that "canceled waves never existed in the
first place" requires a time machine to implement, not
to mention the paradox involved with time travel.

I blew this thread by saying the lasers were "pointed at each other
180 degrees out of phase". You're right, that would cause a standing
wave. If somehow the waves (laser/cohent) could be summed 180 degrees
out of phase in the same direction, then we would have cancellation
and darkness. In that case, where then does the energy go, since it
must be conserved? I believe you had mentioned poltergiests? Is that
your best hypothesis :-)

You either completely misunderstand, or you're deliberately misstating the case. Perhaps both.

Here's what you should do: discover how waves can both cancel and exist simultaneously at any point in time, and you will prove the scientific world and their mathematics to be wrong, Cecil. It's guaranteed martyrdom on scale not seen since Galileo. :-)

Yes, of course you're right about the waves in opposited directions causing a standing wave. Your reference quoted above is the case I was talking about. I was merely pointing out that there are many other groups discussing what happens to energy when it "cancels", knowing that it must be conserved. It is the above situation that I was referring to (embarrasment and humility). I have been properly flogged by Roy and N3LI. Now that we have dispensed with that, can we discuss where the energy goes in the above case, assuming it is not poltergiests as Roy infers?

It's a tossup among poltergeists, Cecil's math, and Art's theories. I'm not sure which would have the best shot at it.

The whole question is pretty much the same as "If pigs could fly, how could they generate enough energy to do it?" Here's a challenge I put forth some time ago, and I'll repeat it now.

Draw a diagram showing how you would get two laser beams to overlap in a straight line as you describe. Feel free to use partially reflecting mirrors, or one or two lasers. Show where all the beams go, including both the transmitted and reflected beams if you use partially reflecting mirrors. I claim that no energy will disappear, and you'll be able to account for every erg of the energy the lasers are putting out, in the form of non-canceled beams. The law of conservation of energy will be obeyed. No wave bouncing, "momentum" altering, or other imagined effects will be necessary to account for all the energy being produced by the lasers. I've been eagerly awaiting the simple diagram which will prove me wrong, but all that appears is more smoke, mirrors (figuratively only), hand waving, and the repeated posing of this and other impossible questions.

Let's look at some of the other possibilities:

1. Dark matter
2. Antimatter
3. Another dimension
4. Somewhere Out There
5. Conversion to an itty bitty speck of matter
6. Carried off by UFOs
7. An exception is made to the law of conservation of energy by your choice of deities, including but not limited to God, Zeus, and the Flying Spaghetti Monster. Or perhaps a dispensation can be purchased from the Pope for a few joules.
8. Into the aether
9. Into Gaussian equilibrium
10. Into other ordinary laser beams, per my challenge

Take your pick.

Cecil,

Many people, myself included, treat the term "interference" in a qualitative manner. The general meaning is that two entities somehow interact in a noticeable way, and the result has some signature of that interaction.

You appear to use a very precise, quantitative definition of "interference." I do not recall ever seeing such a quantitative

definition. Could you please give us a reference or an exact quote from some reasonably reputable source that defines "interference" in a quantitative and unambiguous manner?

You imply that some interactions lead to "interference" and some do not. How can the unwashed among us know when the magic occurs and when it does not?

73,
Gene

Cecil,

I looked at that web page, and my reaction was merely, "so what"? There is nothing in there that is not well known to everyone who has ever used or studied interferometry.

You seem to forget that the entire argument on RRAA in this theme is not about *what* happens, it is about *how* it happens. There is not one person who would seriously claim any violation of conservation of energy to be valid. There is not one person who would be surprised to learn about constructive and destructive interference and the redistribution of energy. Anyone making competent physical measurements would find the same, predictable results.

What *is* at issue is the mechanism involved. None of these web references aimed at the Popular Science crowd even attempt to get into those fine details. You love to quote a web page written by a Java-dude and a lab technician. You love to quote a web page written by a

manufacturer of lenses and other optical components. Now you are quoting a web page from a company who is "dedicated to the design, development, manufacture, and marketing of apparatus appropriate for laboratory instruction in physics and engineering." None of these are necessarily wrong in what they are attempting to say. What *is* wrong is trying to use these popular-level tales in support of your hair-splitting arguments.

Spend some time reading a serious reference on conservation of energy in electromagnetic systems. You will come to understand that your concerns about "wave cancellation" and related stuff at interfaces are not only unimportant, they cannot even be determined by rational analysis. It comes very close to counting the angels on pinheads.

If you really want to dig in further, you will need to start to look at the detailed interactions of the waves with the interface materials, including the scattering formalism. Reflection does not just "happen". I do not suggest going there unless you need some sleep inducement.

Exactly right. In fact it's a perfect example of how energy is distributed without need of ideas like "reflections caused by interference".

If we have two lasers positioned at a right angle to one another, and both are pointing at a beam splitter* oriented at 45 degrees to the light path, assuming the beams are coherent and collinear, we can create light along the path set by laser A and not laser B. If we then change the distance of one of the lasers by half a wavelength we will have light along the path set by laser B and not laser A. The canceled waves carry no energy of course. All the energy is carried by the waves which don't cancel. As Roy suggests, similar experiments having the same results can be done for example with one laser and two beam splitters. But there's more. All of the source energy is obtained using reflectors that are only partially reflective, and there are no other reflective "mechanisms" required.

Now, if you can get the apparatus to work with 100% reflective surfaces, as Cecil has described, you should then be able to get out more energy than you put in. :-)

73, ac6xg

* a beam splitter is a partially reflecting mirror which allow half
the light to pass through, and half to be reflected (i.e. it has a
reflection coefficient of .5).

Actually, a beam splitter could be constructed of a prism, giving a much clearer picture ... and you shouldn't have to "reflect" on that long! <grin>

How about analyzing a vibrating string? If you play guitar, there's a very nice note you can make by plucking a high string, then putting your finger at exactly the correct spot and removing it quickly. The note will jump to a much higher frequency and give a much purer sound. Clearly, the mechanical energy has split into two waves that cancel at the node.

In principle, you could show the node is stationary, thus contains no energy. But there is energy travelling on both sides of the null point - you can hear it.

You can also create other notes by touching different spots on the vibrating string. These create standing waves with energy travelling in both directions, but cancelling at the null points. Very similar to transmission lines.

Actually, those Caddock MP9 and MP8 non-inductive resistors are good to HF (allowing for the physical size). The inductance of the big ones (MP9100, 100W units) is about 20nH, about 3 ohms at 28 MHz. Half that for the smaller ones. The challenge is in getting the heat away from them. the thermal resistance of the MP9100 is 1.5 degrees/W, so at 100W, the resistor is 150 degrees hotter than the heatsink, and with a max temp of 175C, you'd better keep that heatsink at 25C.

It's about 1/2 cm x 1 cm. Say it's 1/2 mm from sink to innards. 8.85
pF/m * 0.5E-4 m^2/0.5E-3m = <1pF....

pretty small.

That's the DC fusing current....

As an earlier poster mentioned, skin effect means that the current is
being carried in a thin layer on the surface, so the heating might be
more. Of course, the hot layer is also closer to the air.

The NEC rules are for mechanical strength, not current carrying capacity.

One might also wonder about corona discharge at the ends of the dipole...

Most undergraduate physics texts have, or should have, discussions of
vibrating strings. There's a good treatment of the subject in
William C. Elmore's and Mark A. Heald's book _Physics of Waves_
published by Dover. If you wanted to get in an argument you could
say that the energy on both sides of the node isn't traveling, but is
merely alternating between potential and kinetic. Such strings have loss

(or you wouldn't be able to hear them). Loss is a taboo subject on this newsgroup because it makes wave behavior too hard to understand for the savants posting here.

> nothing is gained.

Not quite, but close. It's ok to have two waves that cancel at one place but go their separate ways at others without reinforcing. Any combination of canceled, reinforced, and independent waves is ok as long as the energy all adds up to the amount put into the system.

The purveyors of these contrived questions have never been able to explain how they create these exquisite co-traveling canceled waves without also creating those nagging reinforced or non-canceled waves. Since it requires magic to create them, it should be no surprise that it requires magic to explain what happens to the energy once the magical canceling waves have been conjured up.

OK, that is a rational position. You are saying that the premise is
incorrect, that is, all light will *not* cancel when two forward coherent
light beams are superimposed 180 degrees out of phase (as happens with sound
waves and shock waves). Given the premise is invalid, then I withdraw my
question. However, I am sure I have read in some literature that indeed the
premise is true; however, you win the argument because I cannot prove the
premise is true and you have no incentive to prove the premise is wrong (you
only need to say so, and you have). Touche'.

No, I'm not. Please read my posting again. I'm saying that you cannot create those two waves without also creating waves which, together, contain the amount of energy being produced by the laser(s). You can cancel all the light you want. But you can't do it without also leaving or making enough other light to account for the energy being produced.

> Given the premise is invalid, then I withdraw my
> question. However, I am sure I have read in some literature that indeed the

Huh?

I don't need to prove anything. I'm just waiting for someone to show me how he creates those co-traveling canceling waves without also creating enough other waves to account for all the energy being produced by the lasers. (I'm even perfectly willing to accept perfect mirrors, perfectly coherent, phased, and amplitude-matched lasers, and other ideal components.) Then we can take the discussion from there. C'mon, shouldn't take but a couple of minutes to sketch out the system and prove me wrong.

Yes, I thought about that a bit before posting. It seems logical a
plucked string sends a wave in both directions, where it is
reflected and returns to create a standing wave.

When it forms a standing wave, it seems reasonable to say the energy
is alternating between potential and kinetic. But isn't that similar
to what happens on a transmission line that is exactly some multiple
of a quarter wavelength long?

Demo 4 of the TLVis1 program I posted reference to, shows that in a transmission line with a pure standing wave (load reflection coefficient magnitude of 1), the energy between nodes alternates between the electric field (line capacitance) and magnetic field (line inductance). This is true regardless of the line length or the source termination.

Yes, this is a very nice demo. Thank you for posting it.

I have a question. In demo 4, the bottom window shows the Ee field
in green, Eh in red, and ETot in black.

When the demo starts, you can only see a green and a black trace.

If you pause it just as the wave hits the end, you can now see the
red trace, Eh. (This is an actual statement and has nothing to do
with the fact I am Canadian.)

What happened to the Eh trace as the wave is initally moving to the
right? Is it overlaid by the Ee trace in green? Or is it just not
plotted?

Then, when the wave hits the end and starts reflecting, the red
trace remains attached to ground, and the green trace moves up and
connects with the black trace. (Sorry for the confusing description
- you have to try it yourself to see.)

Now, as you single step, the green trace and the red trace appear to
be 180 degrees out of phase.

My problem here is someone wrote a web page that claims the electric
and magnetic fields are orthogonal:

http://www.play-hookey.com/optics/transverse_electromagnetic_wave.html

I tried sending him an email to show if the fields were orthogonal
as he claims, it would look like a pure reactance, and no energy
would be transmitted. But he is stuck on his idea and won't budge.

Now my problem is figuring out exactly what happens at the
reflection, and why the Eh field behaves the way shown in your demo.

I got to thinking about this a little more, and want to reclaim the
"net" modifier.

Hopefully we all agree that on a line with a pure standing wave (unity
magnitude load reflection coefficient), there are nodes at which the
power is zero at all times, indicating that no (and I'll reinsert "net"
here) energy is moving past that point. But there's energy going into

that node at equal rates from both sides during half the energy cycle, and out of the node during the other half cycle. We've used those observations to conclude that no energy is going past the node.

But let's look at another equally plausible explanation. We know we have a bundle of energy from the left and another equal bundle from the right which flow into the node at the same time, resulting in zero power at the node. But suppose that the bundle of energy from the left flows out to the right, and the bundle from the right flows out to the left during the next half cycle (rather than the one from the left flowing back to the left, and the one from the right to the right, as we've been tacitly assuming). Now we've moved energy across the node while retaining zero power at the node (zero power because the amount of energy moving from left to right always equals the energy moving from right to left at the node). A nice thing about this interpretation is that it meshes neatly with the concept of two traveling waves of equal amplitude moving in opposite directions. Does that solve some of the conceptual problems you've been having with the nodes?

Of course, I don't know of any way to put a tag on any particular bundle of energy, so one explanation is really as good as the other from a mathematical standpoint. But I think that the idea of moving the energy past the node relieves us of the necessity, or temptation, of devising various wave interactions to explain how the energy can just stop at the nodes.

And, maybe it'll allow me to resurrect my *net* modifier. If you go along with the new interpretation, energy is moving from left to right through the node and from right to left through the node -- there is energy moving past the node, but no *net* energy movement through the node.

That's right. And we know that intensity is proportional to the square of the EM field, so if P=9 then field=3. When there are two such EM fields superposed, then we have 3+3 squared which is four times greater than 3 squared. And owing to this supposed 'inequality', we have the sophomoric (literally) notion that there is "extra" energy which must come from somewhere else.

The traces are drawn in the order Eh, Ee, and total. During the initial forward wave, Eh and Ee are equal, so the Ee overwrites the Eh trace.

> Then, when the wave hits the end and starts reflecting, the red
> trace remains attached to ground, and the green trace moves up and

Hopefully it'll all make sense once you think about how one trace will always win when more than one have the same value.

You're making the same error that Cecil often does, confusing time phase with directional vector orientation. The orthogonality of E and H fields refers to the field orientations of traveling plane TEM waves in lossless 3D space or a lossless transmission line, at the same point and time. The E and H fields of these traveling waves are always in time phase, not in quadrature. The graphs show the magnitudes of the waves at various points along the line. These represent neither the time phase nor the spatial orientation of the E and H fields.

> I tried sending him an email to show if the fields were orthogonal

Good for him -- he's absolutely correct. If the E and H fields were in time quadrature, you'd have a power problem. But they're not. They're in phase in any medium or transmission line having a purely real Z0 (since Z0 is the ratio of E to H of a traveling wave in that medium). This includes all lossless media. But they're always physically oriented at right angles to each other -- i.e., orthogonally, according to the right hand rule.

Now you are confusing me with Cecil. I have no difficulty with the E
and H field orientation.

> The E and H fields of these traveling waves are always in time

Yes, that's what I tried to explain to him also.

> Good for him - he's absolutely correct.

There is a bad mixup here. He claims:

"Note especially that the electric and magnetic fields are not in
phase with each other, but are rather 90 degrees out of phase. Most
books portray these two components of the total wave as being in
phase with each other, but I find myself disagreeing with that
interpretation, based on three fundamental laws of physics"

He claims the E and H fields are in quadrature. I claim he is wrong.

> If the E and H fields were in time quadrature, you'd have a power
> problem.

I believe that is what I tried to tell him. He bases his argument on the following:

1. "The total energy in the waveform must remain constant at all times."

Not true. It obviously goes to zero twice each cycle.

2. "A moving electric field creates a magnetic field. As an electric field moves through space, it gives up its energy to a companion magnetic field. The electric field loses energy as the magnetic field gains energy."

Only if the environment is purely reactive. Not true with a pure resistance.

3. "A moving magnetic field creates an electric field. This is Faraday's Law, and is exactly similar to the Ampere-Maxwell law listed above. A changing magnetic field will create and transfer its energy gradually to a companion electric field."

Again, not true in a resistive environment.

Yes, there is no confusion about this whatsoever.

It's a no-brainer in a transmission line. If waves are
canceled in one direction, the energy that existed in
those waves before they were canceled goes in the other
direction. We hams call it a reflection.

Actually it is a full wave length helix winding for 160M. The teflon coated wire was what I had on hand.I will only be using 100 watts or so but you never know when the urge comes up. I have a motor driven reflector on it so I will be checking out the directivity at different close spacings.When I finally settle on a design the wire will be thicker magnet wire.
Thanks for all the info. As for heat it is mighty cold here so short transmissions should work out o.k.

I've already posted what Eugene Hecht said about interference.

In the irradiance (power density) equation,
Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(A)
the last term is known as the "interference term", page 388 of
"Optics" by Hecht. Here's another reference:

http://en.wikipedia.org/wiki/Interference

A Google search for "electromagnetic wave interference" yielded
1,650,000 hits.

> You imply that some interactions lead to "interference" and some do not.
> How can the unwashed among us know when the magic occurs and when it
> does not?

If the interference term in the above irradiance (power
density) equation is not zero, then interference is present.

In the s-parameter equation, b1 = s11*a1 + s12*a2, if b1
equals zero while s11, a1, s12, and a2 are not zero, then
total destructive interference is present.

Assume we superpose two coherent, collinear voltages, V1 and V2:

If (V1+V2)^2 > V1^2+V2^2, then constructive interference is
present.

If (V1+V2)^2 < V1^2+V2^2, then destructive interference is
present.

Strawman alert!
To the best of my knowledge, nobody has ever been stupid enough
to say waves cancel and the energy in them is destroyed. In fact,
I have said exactly the opposite, i.e. waves cancel and the energy
that existed in them before they were canceled is preserved.

I believe it is you who is on record as not caring where the
energy goes.

Although I have not completely thought it out, I would be surprised if the same did not hold true for sound waves in a sonic/audio resonator--and, this obviously is ONLY a wave which transverses a media and doesn't harm/displace any photons in the process.

You know those d*mn "photon advocates", worse than the animal rights advocates, actually. :-D

Strawman alert! Roy has gone from zero energy reflected
waves to a much more rational position. Now if he would
only admit his error in using standing wave current to
try to measure the phase shift through a loading coil.

It also satisfies the wave reflection model which tells
us that no reflections can occur in a homogeneous medium.

The intensity is watts/unit-area, i.e. real energy.
If the intensity of the bright rings is 4P there is
indeed greater than average energy which requires a
zero P dark ring somewhere else in order to
average out to 2P. The "extra" energy in the bright
rings comes from the dark rings. The conservation of
energy principle allows nothing else. It is not a
sophomoric notion. It is the laws of physics in action.

Good wakeup call; The discussion has become so convoluted that the original statements, point-of-discussions-beginnings, etc. has become as forgotten as the methods of pyramid construction (after hundreds of posts--spanning multiple threads) ... :-)

When you pluck a string, you are exciting the whole string at once.
If a sound wave of the right frequency impinges on a string
perpendicular to the string's axis, the string will vibrate
sympathetically. In that case, it's hard to justify saying that two
waves are traveling in opposite directions up and down the string.
Nevertheless, the solution of the partial differential equation
describing the motion of the string, as proposed and solved by
the French mathematician D'Alembert, in 1747, is consistent with the
idea of two waves of arbitrary function traveling in opposite directions

on the string. If I were you, I'd find a copy of the differential equation of a wave on a string and compare it to the same equation describing an electromagnetic wave on a transmission line. How similar are the two?

And you're right. I apologize. "Orthogonal" usually refers to spatial orientation, so when you said that he said they're orthogonal, my reaction was that it's correct. But I didn't look at the web page. I see by looking at it that he also says the two are in time quadrature, which of course is incorrect as you say. His "fundamental laws of physics" are certainly different from everyone else's. Thanks for providing a good example of the pitfalls of relying on the web for information.

Again my apology. You do indeed have it right. Incidentally, it's not possible for a medium to have a purely reactive (imaginary) Z0 at any non-zero frequency.

> Ah, great reference. That explains it.

The following s-parameter equation explains what happens
looking into a Z0-match at a point on a transmission line.
For instance:

source--50 ohm coax--+--1/2WL 300 ohm feedline--50 ohm load

```
|
forward a1------------->|
|---->s21(a1)
s11(a1)<----| \
/ | \
/ (+)---->b2 forward
reflected b1<----(+) /
\ | /
\ |---->s22(a2)
s21(a1)<----|
|<-------------a2 reflected
|
```

b1 = s11*a1 + s12*a2 = 0

b1 is the reflected voltage back toward the source

s11*a1 is the forward voltage from the source reflected
back toward the source at the impedance discontinuity.

s12*a2 is the reflected voltage from the load that is
transmitted through the impedance discontinuity.

s11*a1 and s12*a2 are equal in magnitude and opposite
in phase so they cancel in a process which Eugene Hecht
labels *total destructive interference*.

That requires the same magnitude of constructive
interference toward the load and it is contained in
b2 = s21*a1 + s22*a2 = maximum

s21*a1 and s22*a2 are in phase resulting in the maximum
possible constructive interference toward the load.

That's what happens to the energy that existed in the
canceled reflected waves before they were canceled.

There are plenty of basics you can pick up that there's no need to pay the extra to obtain a "design name." From the outside no ones going to know they aren't designer and no ones going to see the label so their a safe bet!

Items such as white jeans, flirty skirts, cotton T's, crocheted shrugs, or shorts can be purchased without the designer name. Also watch for T's put on sale by some of the big online retailers for as much as 50% off. Bluefly.com quite regularly puts DKNY and Rebecca Beeson T's on for a serious reduction in price.

Looking fresh like they just came off the rack is important. If you purchased budget items then you've save quite a few dollars so once they start looking not so fresh get rid of them.

Shoes are another arena where you can save some money. No need to buy designer. Most important is fit and comfort, and of course you need to be certain they'll work with your wardrobe. This season the wedge, as well as flats for the summer season, are in style so have some fun. If you shop carefully you can add several pair for the price of one pair of designer shoes.

Lastly you can save a whole lot of money on your jewelry. Costume jewelry is affordable and the selection is great. If you stick to costume jewelry you can buy pieces for this seasons fashion and not feel bad because you spent too much and they are out of style next year.

There are many good online store with very reasonable prices. Don't forget to have a hunt through your old jewelry as well - you might be surprised at what you find that has made it back into style. Large clunky jewelry is certainly in. As is wood and bone jewelry. Color is making a big statement this year. This is a very fun season because just about

> begin with.

1. Nice job of selective quoting to completely change the meaning of a message. Is that sort of like a line item veto?

2. As for the wave cancellation part, you have many times noted that stuff happens at interfaces or discontinuities. So why is it that you never ever consider what is happening inside those interfaces and discontinuities? Do you suppose the waves simply cancel, reflect, or whatever without assistance from the materials in the interface or discontinuity? Do you suppose that any energy or momentum considerations may need to include the materials?

This is akin to the concept of Thevenin equivalents. The view from the outside is correct and useful. There is no information about what is actually happening on the inside of the Thevenin box. In the same way the wave reflection model as seen from outside the interface or discontinuity works just fine. There is virtually no disagreement about what one would observe if correct measurements were done. On the other hand there is no possibility of figuring out how the waves actually "cancel" or what happens to the energy and momentum without considering the actual physical configuration. That sort of analysis has been done, of course. It gets into all sorts of details on electrons and Fermi surfaces, but strangely enough, it does not require Java applets on web pages.

Unless you want to look at the interactions of waves with materials in some detail, the concern about exactly what happens during a "reflection" is unimportant. The external equations work just fine.

Mike,

This concept is not unique to the web site you referenced. I have seen several other debates about the same thing.

One thing that is missed in this simple analysis is a consideration of the uncertainty principle. Heisenberg proposed in 1927 that it is not possible to simultaneously know the value of position and momentum to arbitrarily high accuracy or to know the value of energy and time to arbitrarily high accuracy.

The uncertainly for energy and time is given as delta E x delta t must be greater than or equal to h-bar, which is Planck's constant divided by 2 pi.

The energy of a photon is h-bar x omega, where omega is the angular frequency of the photon.

In order to declare a violation of energy conservation in the wave example above, one would need to examine the energy at time intervals at least as short as half the wave period. Guess what, the uncertainty principle says that if we attempt to do so we cannot determine the energy to the accuracy required in order to claim a violation of energy conservation. Note carefully that "determine" does not mean we must actually measure the energy. The energy cannot even be defined more accurately than the limit imposed by the uncertainty principle.

One way to look at this is that during the interval over which one might try to claim a violation of energy conservation the energy is in a virtual state. As you may know, this sort of consideration is everywhere when one delves into atomic scale and quantum mechanics.

I guess you didn't notice the thing about the square of the sum of two numbers being four times as great as the square of one of the numbers. It simply means, for example, that a doubling in voltage is a quadrupling in power. It doesn't mean there's "extra" energy anywhere.

> The "extra" energy in the bright
> rings comes from the dark rings.

There really is no extra energy.

> The conservation of
> energy principle allows nothing else.

Conservation of energy doesn't allow for there to *be* extra energy in the first place! That's the most fundamental principle. Putting the word 'extra' in quotes doesn't change that.

remedies for it.

493. The true religion teaches our duties; our weaknesses, pride, and lust; and the remedies, humility and mortification.

494. The true religion must teach greatness and misery; must lead to the esteem and contempt of self, to love and to hate.

495. If it is an extraordinary blindness to live without investigating what we are, it is a terrible one to live an evil life, while believing in God.

496. Experience makes us see an enormous difference between piety and goodness.

497. Against those who, trusting to the mercy of God, live heedlessly, without doing good works.--As the two sources of our sins are pride and sloth, God has revealed to us two of His attributes to cure them, mercy and justice. The property of justice is to humble pride, however holy may be our works, et non intres injudicium, etc.; and the property of mercy is to combat sloth by exhorting to good works, according to that passage: "The goodness of God leadeth to repentance, and that other of the Ninevites: "Let us do penance to see if peradventure He will pity us." And thus mercy is so far from authorising slackness that it is on the contrary the quality which formally attacks it; so that instead of saying, "If there were no mercy in God we should have to make every kind of effort after virtue," we must say, on the contrary, that it is because there is mercy in God that we must make every kind of effort.

498. It is true there is difficulty in entering into godliness. But this difficulty does not arise from the religion which begins in us, but from the irreligion which is still there. If our senses were not opposed to penitence, and if our corruption were not opposed to the purity of God, there would be nothing in this painful to us. We suffer only in proportion

I think what he means is, how does the second know which way the
aether is pointing and why does it care?

Steve:

You know I can hardly wait to lay hands on the darn thing; and, you know it will live with me for a day and, THEN, I will have the case off it.

You did see the sentence which acknowledges it has an ITX board in it (a miniature motherboard!) In effect, I am just buying a computer which knows how to be a radio ...

I tell you, I think it is enough. I do believe I will be happy with it. It is NOT like buying gold, I know it has a life expectancy and one day that will be $0.01 USD.

Still, I will be happy for a bit ... as I said, you mileage may vary. I walked into this deal with my eyes wide open ...

Warm regards,
JS

that we possess
slipping away.

213. Between us and heaven or hell there is only life, which is the frailest thing in the world.

214. Injustice.--That presumption should be joined to meanness is extreme injustice.

215. To fear death without danger, and not in danger, for one must be a man.

216. Sudden death alone is feared; hence confessors stay with lords.

217. An heir finds the title-deeds of his house. Will he say, "Perhaps they are forged" and neglect to examine them?

218. Dungeon.--I approve of not examining the opinion of Copernicus; but this...! It concerns all our life to know whether the soul be mortal or immortal.

219. It is certain that the mortality or immortality of the soul must make an entire difference to morality. And yet philosophers have constructed their ethics independently of this: they discuss to pass an hour.

Plato, to incline to Christianity.

220. The fallacy of philosophers who have not discussed the immortality of the soul. The fallacy of their dilemma in Montaigne.

221. Atheists ought to say what is perfectly evident; now it is not perfectly evident that the soul is material.

222. Atheists.--What reason have they for saying that we cannot rise from the dead? What is more difficult, to be born or to rise again; that what has never been should be, or that what has been should be again? Is it more difficult to come into existence than to return to it? Habit makes the one appear easy to us; want of habit makes the other impossible. A popular way of thinking!

Why cannot a virgin bear a child? Does a hen not lay eggs without a cock? What distinguishes these outwardly from others? And who has told us that the hen may not form the germ as well as the cock?

223. What have they to say against the resurrection, and against the child-bearing of the Virgin? Which is the more difficult, to produce a man or an animal, or to reproduce it? And

Roy Lewallen wrote:
"I got to thinking about this a little more, and want to reclaim the
"net" modifier."

Researching my trusty 1955 Terman opus, I find on page 91, Fig. 4-3, "Vector diagrams showing manner in which the incident and reflected waves combined to produce a voltage distribution on the transmission line."

Exactly 1/4-wave back from the open-circuit load, the incident and reflected voltage vectors are out-of-phase resulting in a minimum voltage point on the line. On page 92, Fig. 4-4 shows that the minimum voltage point is also the maximum current point.

The energy does not go away at minima on the line but merely shifts from the electric field to the magnetic field or vice versa.

Hi Cecil -

I went ahead and corrected your drawing. At least that's what I think you meant for it to show.

> That's what happens to the energy that existed in the
> canceled reflected waves before they were canceled.

Does "before" mean before steady state? Because according to the s parameter equation you provide, as long as they are equal and opposite, s11*a1 and s12*a2 are always cancelled.

That's one of the points I have been trying to make. The impedance
discontinuities perform the same function as half-silvered mirrors,
for instance, in interferometers. The impedance discontinuity is a
primitive interferometer.

> On the other
> hand there is no possibility of figuring out how the waves actually

The point is that optical physicists already had it figured
out before any of us were born. The problem is that RF gurus
tend to reject any technical facts from the field of optics.

You, for instance, called me every name in the book while
arguing loud and long against any of those concepts from
the field of optical physics. Now you admit that some of
them are valid but completely unimportant. That is, at least,
an improvement.

It happens too fast to capture on a scope but if it doesn't
happen, the s-parameter analysis is just BS. Is that really
the argument for which you want to be remembered?

By the process of elimination, we know the above interaction
actually happens in reality. If, as you say, it doesn't happen,
the conservation of energy principle is violated.

I see you have, so far, refused to perform the simple calculation
that would prove what I have been saying to be correct. I don't
blame you for refusing.

On the contrary, constructive interference cannot happen
without that "extra" energy sucked up from destructive
interference (or from a local source). That's what you
are completely missing. Constructive interference between
two waves requires more energy than exists in those two
component waves. In the absence of a local source, another
two waves *must* be engaging in destructive interference
at the same time in order to supply the constructive
interference.

> Conservation of energy doesn't allow for there to *be* extra energy in
> the first place!

Therefore, those bright rings are just an illusion and
don't contain more than the average energy in the two
superposed waves. I guess that's your story and you
are sticking to it.

I guess by now it won't come as a surprise to anyone that you believe something like that. What's surprising is that you expect someone else to. The truth is, the s-parameter analysis just says that the waves cancel. You made up the rest.

So in other words if you're wrong, then what you're saying violates conservation of energy.

It has been very cold these last few days working on antennas. Just
finished putting up anew
160M antenna but have not checked it yet as I am so tired.It is like a
TV antenna at 70 feet.
Have a reflector on it made of aluminum mesh plus a motor to place the
reflector within six inches of the driven element to about 30 inches
from the driven element.Now have to wire up the rotor and the
reflector motor and then chart the LC for all bands.HopefullyI will be
close first time for the top band.Next antenna to brew will be around
1 cuft for 160M probably out of #20 wire this time but I do need a
rest from antennas!

>
> Does "before" mean before steady state? Because according to the s
> parameter equation you provide, as long as they are equal and opposite,
> s11*a1 and s12*a2 are always cancelled.

No, "before" does not mean before steady state.
a1 is the *continuous steady-state forward voltage*.
s11 is the reflection coefficient seen by a1.
s11*a1 is the reflection that is being *continuously*
generated during steady-state. It is canceled immediately
after it is generated. It is impossible for it to be
canceled if, as you say, it never existed in the first
place. You continue to confuse cause and effect. Wave
cancellation is an effect. It cannot happen before its
own cause. Your concepts require a time machine.

From cause to effect in time sequence:
Given: a1 and a2 exist as continuous plane waves
all during steady-state.

Step 1. s11 causes s11*a1 and s12 causes s12*a2.
This step occurs at t(n). Step 2 then occurs at
t(n)+dt. As is usual in differential calculus,
the difference between t(n) and t(n)+dt cannot
be measured with instruments.

Step 2. wave cancellation immediately causes their
sum to go to zero in the original direction of travel.
Their combined component energies are redirected
in the other direction as constructive interference.

We know the two waves are canceled. There can be no
wave cancellation if the waves never existed. Therefore,
the waves *must* exist all during steady-state.

I'm sorry, but that is the way the time-honored wave
reflection model works. In optical physics, it is
the time-averaged value of the square of those terms

that is used. Time averaging signals that you say
never existed in the first place will, no doubt, drive
you up the wall. You either accept the time-honored,
time-proven math model or you don't.

And you say the waves didn't cancel - that they don't
even exist during steady-state. Take your pick about
who is correct. If two waves cancel, as the s-parameter
analysis says they do, it implies that they must first
exist even if for only a dt of time.

HP never considered anyone dense enough to require an
assertion about the very existence of the s-parameter
equation components.

You couldn't be more wrong in your interpretation.

Perhaps you will understand it this way: the bright rings have an intensity which is equal in energy to the sum of the energy in the two superposed waves. Energy doesn't have to come from anywhere else to balance the equation.

The error you're making is the assumption that since the intensities don't add up, something has to come from somewhere else. But that's a wrong assumption to make. One shouldn't expect intensity to add like that. Obviously it doesn't add like that. The fields are what add and subtract, not intensity (or power). Power is the time derivative of energy - that's the reason a squared term comes in. But power and intensity don't propagate, therefore they don't superpose, and shouldn't be added algebraically. Fields, voltage, current, energy - it makes sense to sum those things algebraically.

When you double something and then square the sum, you get a factor of four. But you're still only doubling the 'thing' of interest. Depositing two paychecks and squaring the sum doesn't make your bank balance go up by a factor of four. But it is certainly true that you would have to borrow money from someone to make that happens. The point is that it's not a realistic expectation.

I assume you know that the meter face on your Bird wattmeter is calibrated exponentially. So, when your Bird power meter reading goes up by a factor of four, what do you think the voltage across its meter movement has actually increased by? The thing is, the Bird company understands that when power reading quadruples, the circuit voltage has only doubled. You'll note they don't claim that since the reading quadrupled instead of doubling, the "extra" power had to come from somewhere else.

If you can't understand this, that's fine. But it's not an excuse to get so bloody belligerent with people about it.

1458. Derivation of Reflection Coefficient vs SWR

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-25 03:33:35 UTC
From: Roger Sparks <rsparks@elltel.net>
Message-ID: <Noednf69voETxQTanZ2dnUVZ_uOmnZ2d@neonova.net>
Source record: 28878

It is not too hard to use the concept of traveling waves and reflections to derive the familiar reflection coefficient to SWR relationship. SWR is a measurable and useful relationship that most hams are familiar with. A clear path between SWR and traveling waves should make the concepts more understandable and believable.

Power placed on a transmission line is placed over time. No matter how small the time span interval we might want to examine, the span will always be wide enough to include some quantity of power or energy. If we desire, we can eliminate the time consideration and just consider energy, but there is no need to do that. In this derivation, the distinction between power and energy will be ignored.

We will assume that neither power nor energy can be stored at the discontinuity in amounts greater than the natural storage capacity of the lines. This assumption fixes the impedance of any waves to the impedance of the transmission lines.

Begin the derivation by assuming that power is applied to a transmission line with impedance Zo. A traveling wave moves down the transmission line to a discontinuity which is composed of a second transmission line or resistor with impedance Zl. The junction between the two lines is like a window or thin plane, with Zo on one side and Zl on the other.

Upon encountering the discontinuity, the lead edge of the wave (and all following energy levels) follow a "conservation of energy" rule that requires energy to be preserved at all times. In other words, the energy that has been conveyed to the junction by some interval of applied power is not lost to heat, radiation, or storage, but will leave the junction as fast as it arrives, and can be located, maintaining time shape.

The following equation will be valid,

Pf = Pl + Pr

where Pf = power forward, Pl = power to load, and Pr = power reflected.

Use the voltage equivalent,

(Vf^2)/Zo = (Vl^2)/Zl + (Vr^2)/Zo

where Vf = forward voltage, Vl = load voltage, and Vr = reflected voltage. The reflected wave will travel back down the main line with impedance Zo.

Simplify the equation by rearranging and substitute SWR = Zl/Zo

(Vf^2)/Zo - (Vr^2)/Zo = (Vl^2)/Zl

SWR(Vf^2 - Vr^2) = (Vl^2)

Change the Vl into terms of Vf and Vr. Vl = Vf + Vr. We can do this because at a reflection, traveling waves double back over one another, adding voltage. Substitute Vl = Vf + Vr

SWR(Vf^2 - Vr^2) = (Vf + Vr)^2

Factor the polynomial on the left above

SWR(Vf - Vr)(Vf + Vr) = (Vf + Vr)^2

Divide both sides by (Vf + Vr)

SWR(Vf - Vr) = Vf + Vr

Divide both sides by Vf

SWR(1 - Vr/Vf) = 1 + Vr/vf

Vr/Vf = Reflection coefficient Ro, substitute

SWR(1 - Ro) = 1 + Ro

Rearrange to put Ro on one side

Ro + Ro*SWR = SWR - 1

Factor out Ro and rearrange

Ro = (SWR - 1)/(SWR + 1)

We have found the familiar relationship for the Reflection Coefficient (Ro) and SWR using traveling wave logic.

Using identical logic but using current instead of voltage, the same relationship can be found from

Zo*If^2 = Zl*Il^2 + Zr*Ir^2

By examining this derivation, the reader can see that power and energy is reflected when a wave encounters a discontinuity. The reader can also see that more power is present on the transmission line than is delivered to the load.

Here is a link to additional information about transmission lines:

http://www.astrosurf.com/luxorion/qsl-transmission-line2.htm

No. Any field generated by s11*a1 would at any time negate a field
generated by s12*a2, and vice versa.

> Step 2. wave cancellation immediately causes their
> sum to go to zero in the original direction of travel.

Not only that, wave cancellation immediately cancels any
electromagnetic fields that might be attributable to either wave.

> Their combined component energies are redirected
> in the other direction as constructive interference.

Allegorically speaking.

> We know the two waves are canceled. There can be no
> wave cancellation if the waves never existed.

Correction. There can be no waves if there is field cancellation.
The conditions that cause cancellation of fields would thereby prevent
the propagation of waves.

> Therefore,
> the waves *must* exist all during steady-state.

That's very poor logic. You should know better.

> I'm sorry, but that is the way the time-honored wave

You are supporting my point exactly. There is little mystery about what happens *outside* the discontinuity. At the same time, saying something functions in the manner as half-silvered mirrors adds nothing to the technical discussion. You continue to argue mechanisms, in the style of "It [reflection] is canceled immediately *after* it is generated." Yet there is no discussion or even recognition of the physical processes that are going on. This leads to endless arguments that are little more than counting angels dancing on pinheads.

I think you must be confusing me with someone else. I just went back to look at the messages I sent over the past three months. I could not find a single case where I called you any name at all, much less every name in the book. Do you consider it name calling if I disagree with you? That would explain a lot, including all of the names you have called me.

I have been a physicist working in the optics field for several decades. I have no particular difficultly with any of the concepts. What I do have difficultly understanding is someone who extrapolates valid concepts beyond their realm of applicability. The irradiance equations work fine for detailing the external effects, but they don't give any hint of what happens inside the interface. Think Thevenin.

I have read in the literature that, although multiple particles, (photons or mass) cannot exist at the same time and place simultaneously, waves can and do exist in the same time and place simultaneously. If the waves that add (superpose to double amplitude) coexist at the same time and place, so do the waves that subtract (superpose to zero amplitude). These waves all can also coexist and superimpose with other waves of unrelated origin in the same place, with different frequencies and so on. Thus, you cannot assert that, just because there is an absence of energy, the waves never were permitted to coexist. You can only say they coexist at the same time and place but superpose to zero. This is offset by the waves whose amplitudes superpose to double amplitude at a different place at the same time. The energy in the waves that added in a defined volume were calculated by squaring the doubled amplitudes (energy X 4). The energy in the waves that superimposed in a defined volume were calculated by squaring zero (energy X 0) with a time average in the defined volume of (energy X 2) where we see that energy is conserved in the system by summing the energies of the 2 original waves.

>> Therefore,
>> the waves *must* exist all during steady-state.
>
> That's very poor logic. You should know better.

No, it is true, The wave model works exactly like that.
If you go to the particle model, you must deal with a much more complicated quantum mathematical model (Schrodinger wave equations) that looks at probabilities of particles existing at certain places and times but the result will be the same, energy will be conserved, within the allowable uncertainty factor.

Hi Gene,

Cecil isn't going to rise far enough to catch a breath of air on this
one. You may as well drop the shoe for lurkers (and me).

I don't see the connection to Thevenin (specifically); but, for me,
inside the interface we can draw the correlation of TIR failure (the
chapter that Cecil hasn't drug across the Xerox yet) to evanescent
waves to near fields to how antennas work.

> balance the equation.

That just shows that you still don't understand the
interference process. The bright rings have an intensity
which is equal in energy to *double* the sum of the energy
in the two superposed waves. If P1 = P2, the total energy
in the bright rings is P1+P2+2*SQRT(P1*P2) = 2*(P1+P2).

That "extra" constructive interference energy has to come
from somewhere and it comes from the dark areas where
destructive interference occurs. In the dark areas,
P1+P2-2*SQRT(P1*P2) = 0. Taking the average of those two
equations yields (P1+P2) which is the sum of the energy
in the two superposed waves. That's only half as bright
as the bright rings.

The constructive interference energy has to exactly equal
the destructive interference energy or else the conservation
of energy principle is violated and, sure enough, they do
equal each other.

It's reasonable, though. Looking at demo 4 with the TLVis1 program, you can see that there's power all along the line except at specific nodal points (where I or V is always zero), yet there's no power at all being delivered to the load.

The fields (waves) contain energy which must be conserved
and momentum toward the source which must be conserved.
Since that energy doesn't flow toward the source,
it is redistributed in the only other direction
possible, i.e. toward the load. We hams call that
reversal of momentum a reflection. If you perform the
analysis using phasor voltages, the destructive
interference on the source side accompanied by an
equal amount of constructive interference on the
load side is obvious.

It is akin to destructive interference at the standard
output causing constructive interference at the non-
standard output in the previously posted example.

http://www.teachspin.com/instruments/moderni/experiments.shtml

What is it about the equality between destructive
interference and constructive interference that you
don't understand?

You said the waves don't exist during steady-state.
Waves that don't exist are incapable of canceling.
Therefore, you said the waves don't cancel. This
is just one example of your confusing cause and
effect and tying your argument into a Gordian knot.

Roy, my though was that on anything but a lossless line with VSWR=1,
instantaneous power (being the rate of flow of energy) varies with time
and location, so to make the statement that "power is present" and to
quantitatively compare it with the power at a point (being the end of the
line where the load is attached) seems to not be so reasonable.

If the statement is about average power in both cases, then it is
reasonable, obvious even, that power decreases with distance from the
source.

Perhaps "power is present" is an avoidance of the somewhat tautological
form "power flows to the load".

The key point is that any field generated by s11*a1 contains joules as one of its dimensions. Any field generated by s12*a2 contains joules as one of its dimensions. Those joules cannot be canceled out of existence and can only be redistributed in the only other direction possible in a transmission line as what we hams label "a reflection". Your "negation of fields" is the same phenomenon that I have been calling "wave cancellation". You cannot have a "negation of fields" without the existence of fields and those fields contain energy that must obey the conservation of energy and momentum principles.

You are very slowly coming to the same conclusion that I came to three years ago, just in different words that mean the same thing and have the same result. In fact, instead of "wave cancellation", I probably should have been using the term, "wavefront cancellation", which would make it identical to your "negation of fields".

Cecil,

You got it right. There is no "inside" to a plane. There is also nothing that happens exactly in that "plane". The real world does not exist in a "plane". You continue to use ordinary external models to try to determine how the "in-plane" action really occurs. Waves go into the interface (plane, discontinuity, whatever) and they come back out. There is nothing in these ordinary wave models, including the optical irradiance models, that tells exactly what goes on inside the interface. Even the vaunted s-parameters don't say anything about what happens to cause reflections or other properties. They only say what one would find from measurements made external to the "black box". (Yes, that is a term used by H-P in AN 95-1.) Of course those external measurements are exactly what most people would care about, and that is the main reason for creating s-parameter formulation in the first place.

What do you suppose your ol' pal Occam would say about a model that requires waves to be created and then immediately canceled?

Richard,

Perhaps I have misread the message traffic for the past 5 years or so, but it appears that most of the heat over wave reflections is about what happens during the reflections, including detailed concern about energy and momentum. The issue is never (or at least rarely) about what one would find in external measurements on the transmission line (or free space, as the case may be). This goes back at least to the battles between Steve Best and Walt Maxwell. (I pointed out that both models were correct, although they arrived at the proper conclusions in quite different manners.)

More recently, we have great battles over interferometers and cute Java demonstrations. Absolutely nobody would question the overall wave superposition principles shown in the FSU Magnet Lab Java applet. Most people know how to add sine waves, or at least they can look up the technique. The entire debate usually comes down to arguments about how that addition actually takes place physically. This is what I am calling the Thevenin equivalent. In particular, the external observations are unambiguous and non-controversial. The standard models and equations give all the correct answers for the observables. At the same time those models and equations say nothing about how the two FSU input waves suddenly jump together to superpose and interfere. Do the waves

"cancel"? Is there a requirement for auxiliary waves that are created and immediately destroyed? How does one account for missing momentum?

That attempted under-the-hood analysis with tools suitable only for external description drives my suggestion of the parallel to the Thevenin model.

> model.

the Thevenin (or Norton) equivalent circuits i believe are rarely used in analysing transmission lines and antennas, they are more commonly used for breaking down lumped circuits and networks. In fact Jackson doesn't even have them in the index of Classical Electrodynamics 2nd ed... It is mentioned in Ramo,Whinnery, and VanDuzer Fields and Waves in Communications Electronics in the index, but in scanning the 2 chapters it is listed for i don't see an actual reference to Thevenin... one of those chapters deals with microwave networks and components and does break them down into lumped equivalents so that is probably where the reference belongs, the other chapter wouldn't seem to be related so may be a typo.

The problem with the use of the Thevenin or Norton equivalents is that you have to exactly respect the limitations in order to use them properly... that is the part of the circuit being replaced with the 'black box' equivelent must be linear and time invariant, and the analysis is only valid for sinusoidal steady state. This last one is what gets everyone, it eliminates all the transients and makes it impossible to use to figure out what happens when that first reflection physically happens... you have to ignore all that stuff and only consider the steady state solution.

We have seen that some posters on here don't want to accept those limitations as they try to figure out 'what is in' the black box equivalent... this is of course a non-sequitar as the whole purpose of replacing a part of a circuit with the Thevenin equivalent is to simplify the problem so you don't have to know what is inside and can focus on the rest of the problem. So any attempts to measure the length of the line in the black box, or figure out if it is a lumped circuit break the rules for using it in the first place.

Conceptually, it happens exactly *at* that plane. For
instance, in the following example, a plane is drawn
through the connection points which can be made as
physically small as needed - certainly small enough that
nothing needs to be hidden inside a black box in order
to obfuscate the technical facts.

Plane

This is an example of a primitive one-dimensional
interferometer.

> What do you suppose your ol' pal Occam would say about a model that
> requires waves to be created and then immediately canceled?

He would ask you: "How can waves be canceled if they don't
exist in the first place? If they don't exist in the first
place, why are anti-reflective thin-film coatings ever
required?"

Optical physicists go to great lengths with expensive
interferometer equipment to cause the steady-state
creation and immediate cancellation of wavefronts.
It happens all the time as in the following example.

The following web page describes an interferometer that
creates wavefronts only to have them immediately canceled
at the standard output. It even captures the energy reflected
from those canceled wavefronts and routes it to the non-standard
output.

http://www.teachspin.com/instruments/moderni/experiments.shtml

"Using Dielectric Beamsplitters to find the "missing energy"
in destructive interference"

"Where is the energy of the light going in an interferometer
adjusted for destructive interference? Below is a schematic
diagram showing a way to detect the non-standard output of a

Michelson interferometerï¿½the *light heading back* toward the
laser source. ... Quantitative detection demonstrates that the
standard and non-standard outputs of the interferometer are
complementary. That is, when interference is destructive at
the standard output, it is constructive at the non-standard
output."

What is it about interferometers that you don't understand?

If you assert that a statement by a person is a lie,
you are calling that person a liar. Most likely, he
is not a liar but is merely mistaken. I have been and
will be mistaken again.

The fact that your "sensitivity training" taught you
a more politically correct method of calling a person
a liar is just one more way to create a diversion from
the technical subject matter.

I can just see you drinking at a bar in the old wild
west and trying to explain to an armed and angry
cowpoke that when you said what he uttered was a lie,
you weren't calling him a liar. :-)

I treat people the way they treat me, Gene. Cool your

Ramo and Whinnery warn against even trying to calculate
the power dissipation inside the black box - something
that is regularly attempted on this newsgroup. The
calculated power dissipation inside a Thevenin equivalent
and a Norton equivalent can result in an infinite difference
even though they are both "equivalent".

My parents 90's Buick had the antenna embedded in
the windshield so it's nothing new.

Nothing mysterious was hinted with the words "power is present".

As I finished writing the post, I wanted to call attention to the assumption that the reflected power is true power and adds to the amount of energy "stored" on the transmission line. But "stored" is a word that implies static conditions, and static conditions are not found on a transmission line. So I substituted "present" for "stored.

The amount of energy existing in a transmission
line is exactly the amount required to support
the measured forward power and reflected power.

If the steady-state forward power is 200 watts,
the reflected power is 100 watts, and the lossless
transmission line is one microsecond long, it
contains 300 microjoules of energy. I don't
think that is a sheer coincidence. :-)

That's not true. A Thevenin or Norton equivalent generator can produce a voltage or current, respectively, which is any function of time. This of course includes single pulses and pulsed sinusoids, as well as an infinite number of others.

Gene Fuller wrote:
"Waves go into the interface (plane, discontinuity, whatever) and come back out."

A conductive plane produces a reflection and a phase reversal.

Terman writes in his 1955 opus on page 92:
"(Transmission Line with Short-circuited load.) However, the reflection now takes place with reversal in phase of the voltage without change in the phase of the current. The result is that the current in each wave at the load is half the load current, while the voltages in the two waves add up at the load to a resultant of zero voltage as obviously required across a short circuit."

A better reason to avoid "stored" is that power isn't stored at all, anywhere. Anyone who believes so should be able to tell us how many watts of power are stored in a 50 Ah, 12 volt battery.

If you can find any difference at all between the case where two waves
of equal and opposite amplitude, traveling in the same direction, at
exactly the same time, in exactly the same space, in which there exist
no measureable fields of any kind, and the case where there are no
waves at all, I'd be glad to know about it. Otherwise, I'll continue
to assert the point of view expressed in physics texts on the subject.

Hi Gene,

This behavior exhibits the failure of rote science in the face of
experience and there are many here who flip through a book to replace
thinking or stepping up to the bench.

This harkens back to Cecil's inability to come to terms with the
failure of anti-glare glass of some years ago. As it applies to this
current debate these discussions are not found in school books, except
by parts - and even rarely there as some of the topic transcends their
derivative coverage. Putting editorialization aside (wagging fingers
at fools only fixates their gaze), let us proceed into the interface,
a dimension of greater than 2 dimensions (the so-called plane in other
correspondence).

Thumb through all the favorite "Optics" books, and I dare say none of
them really dwell on the research with Plasmonics that has been
carried out around the world at a hundred or more laboratories. I
feel full well confident in this expectation because every time I
introduce this word (Plasmonics) it is met with universal HUH? I have
no illusions that this posting will raise any but one or two reader's
consciousness on the subject - and even then I am probably
over-estimating interest, or capacity.

Thumb through all the favorite "Optics" books, and I dare say FEW
dwell on Frustrated Total Internal Reflection. Of those few, perhaps
in the appendix.

Thumb through all the favorite "Optics" books, and I dare say some
dwell on Evanescent Waves. Of those some, perhaps in other terms if
they cover the physics of it at all. The good "Optics" text will.

Thumb through all the favorite "Optics" books, and I dare say NONE
dwell on antennas. Not even in the appendix.

Plasmonics reveals the energy relationships at the interface, at each
side of it, and within the media which are separated by the interface.
This word (Plasmonics) merely applies a new label to the old wine of

other disciplines, but those who coined the label, are performing far more profound probing of the interface than those older vintners.

A Plasmon is the energy on the other side of the reflecting interface. This necessarily gives rise to the third (non-planar) dimension of depth (or a new, thick plane, which is to say, not what has been typically discussed). The fields found on the other side of the 2D plane (that is, within the second media) are what is responsible for reflection and provide the complete mechanism. This much is covered already by conventional "Optics" and "RF" teaching, so Plasmonics is not a discovery, nor is it introducing a novel concept - except to those who skimmed their assigned reading, skipped classes, and shaved points off their exams when tests revealed their shortfall of study. I won't repeat that material here. Suffice it to say that reflection mechanics are found in the boundary layer - not in the Xeroxed math from the concluding paragraph of a chapter.

When we approach the "Optics" of reflection, there, too, conventions are suggested by math that solutions are unspoiled by reality (anti reflective glass is chief among these to fail in the real world). The benchmark of reflection is found in the right angle glass prism. This standard, by math, exhibits what is so distinct as to ascend to capitalization, chapter heading, and study title: Total Internal Reflection. This standard even deserves its own acronym TIR. Every "Optics" text champions this standard, but few move on to its failure. Failures are left for advanced study, as academia has enough work to teach success. Experience that follows graduation is thoroughly acknowledged as introducing acolytes to reality and providing actual learning. I will not dwell on the material of Total Internal Reflection, as the reader to this point is undoubtedly aware of either the mechanics, or the implication.

The evidence of Frustrated Total Internal Reflection arrives by the application of the same standard: the glass prism, classically two of them (although this is not strictly required). When two prisms are joined, then light will pass through them both (there is no TIR exhibited). When both are removed a substantial distance, then light entering the first prism will be returned back to the source (offset by the geometry of internal reflections). However, when that separated, second prism is drawn closer to the first, without touching it, but within several wavelengths of that former join, then light will again transit BOTH prisms. TIR has failed, hence the term "Frustrated Total Internal Reflection."

This example, supported by evidence, finds the two prisms isolated one from the other. If the 2D plane of the reflective surface of the first prism was all that was necessary to provide reflection (that is to say, to the neglect of the 3D boundary layer); then this neighboring prism would have absolutely no effect and TIR would not fail. However, it does, and with that failure goes the notion of the 2D plane providing all the substance of reflection. Naturally, this

is already covered in conventional "Optics" books, but the demonstration is almost universally surprising. I am sure many readers who have made it this far are agog how light can leap between two prisms.

The answer (a conventional one) is that the boundary beyond the first prism face supports fields that provide the mechanics of reflection. What is more interesting, is that when a second interface inhabits the same region of waves, they couple across and provide a transmission mechanics to pass light on through the second prism.

So, we find there is a defined region of waves that first accounts for reflection, and secondly that same defined region accounts for transmission. In the study of Plasmonics, these waves are called Plasmons, or are expressed by specialized "Optics" as evanescent waves. The characteristic of these Plasmons or evanescent waves is that they do not persist beyond several wavelengths, and exhibit "zero net energy." These two are not novel concepts discussed here, but it appears that such information is not knowledge for many.

Basically, evanescent waves are what we characterize as the near field of an antenna. Those with the information, but lacking the knowledge may roll their eyes - after all, they "knew it all the time." If only professors accepted such demonstration of learning, colleges would be awash in Phi Beta Kappas.

I will provide some practical examples of this last that correlate to the nearly joined prisms. Harkening back to the work of N. Tesla in my hometown of Colorado Springs; he once set out to establish a commercial means to transmit power without wires. Same stuff. The trick to the success of this has been reported in these threads as discussion trivia (certainly no intelligent thought beyond the simple skill of browsing ever entered into the discussion). The Google topic is how in the future we can recharge our iphone/ipod/laptop by simply being in the same room as a special power antenna.

Here, again, the mechanics have been known for at least 100 years or more (and we don't even need to lean on Tesla to reveal them). Those mechanics, as in evanescent waves, as in Plasmons, as in Frustrated Total Internal Reflection, are found in proximity and the 3D boundary layer. You with your iphone/ipod/laptop are merely inhabiting that layer. The latest research demonstrates that a tuned but lossy load (the drained battery or a light bulb) can effectively absorb up to 60% of that available power from the (long wave near) field (not generally called a Plasmon, and rarely described as evanescent). This is a no more complex relationship than that between a driven element, and a director or reflector (except for the novel application of a tuned load).

I chose the iphone for another reason (rather than for the "hip" factor) because it also reveals Plasmons, evanescent waves, and the application of Frustrated Total Internal Reflection in its interface

(which is a "hip" factor). ;-)

The iphone's unique (and patented) "Optical" interface relies on the 3D boundary layer of your fingers doing multiple touch manipulations (if you are "hip" enough) of images, files, and operations with its screen. I will leave the readers to Google this.

If you are an international traveler, you may have noted a small windowed box at the border control (another interface, but I won't stretch that point) that travelers use to provide fingerprint information. Similar gizmos also are sold for security access to laptops where the user wants a single password (actually the fingerprint as proof of identity) access. These instruments, too, employ Frustrated Total Internal Reflection. I won't belabor the obvious mechanics here.

So, a discussion of the complex reflection (and refraction too) 3D interface employing examples from Plasmonics, Frustrated Total Internal Reflection, Evanescent Waves, Near Fields, and Antennas.

And now for a bit of finger wagging to mesmerize the fools once more. How is it that waves are influenced by other waves in the absence of an interface or load? How is it that numerical coincidences prove/disprove energy/power cannot migrate past lines drawn in the sand of math?

Yep, and if we quickly replaced the source with a termination having the impedance of the transmission line, 100 watts of power would continue to be delivered to the load for one microsecond, delivering 100 microjoules of energy. 100 watts of power would be delivered to the reflected wave termination for two microseconds, delivering 200 microjoules of energy.

The transmission line was a dynamic power storage device for two microseconds after the power source was disconnected.

Roger,

If you were wanting to mean "stored", perhaps it is energy that is stored (over a non-zero length of line) rather than power. In that sense, energy is "present" on the line, and the load may store energy (only if it has reactive elements, and irrespective of whether it looks resistive at its terminals).

I highly recommend the lengthy message just posted by Richard Clark. It captures quite nicely what I have been merely hinting at. In summary, "conceptually" simply doesn't cut it for resolving the fine details of reflections. Nothing happens exactly *at* a plane in the real world. And this is not just a "dx" or "dt" type issue. Real things happen over real distances.

I think everyone agrees that energy is stored on a transmission line in the sense that energy enters at time one and does not exit until some time later at time two.

It is important to be aware that the time shape of the energy package is preserved on a transmission line. The time shape information is contained in the power term for every instant of passing time.

I can understand why many hesitate to think of power as being "stored" on a transmission line, because at best, such storage is dynamic and fleeting. Thinking of power being "present" on a transmission line is better than "stored" because the concept of a time component is not lost.

A plane drawn through the junction of two different
Z0 feedlines also produces a partial reflection.
The reflection coefficient at an impedance discontinuity
is (Z02-Z01)/(Z02+Z01).

The difference in those two outcomes is the conservation of
energy principle at work.

Two waves interfere and cancel. Their combined energy
components (2*ExH) go the other direction in a feedline.

There are no waves. Their combined energy components
equal zero.

That's an infinite percentage difference.

My failure????? You are the one who said the reflections
from an anti-reflective thin-film coating are brighter
than the surface of the sun. And you proved it by
superposing powers.

For anyone who wants to understand anti-reflective
thin-film coatings, here is an example:

http://www.w5dxp.com/thinfilm.GIF

What is the total reflected power at t3 when the
external reflection of 0.01 watts is interfered
with by the first internal reflection of 0.009801
watts. Hint: It is NOT (0.01w - 0.009801w) as
Richard C. earlier calculated it to be.

If it were "exactly the same", the conservation of energy
principle would be violated. Every way you attempt to
explain it results in a contradiction. Hint: Contradictions
are only possible in a human mind - not in reality.

The total result of wave cancellation is infinitely
different from nothing.

Are you sure?

Check your answer by trying 100 kHz sinusoidal
steady-state excitation.

Even easier, ignore the reflected power and
test your assertion just for the forward power.

For fun, work out the line lengths for which your
claim is true.

Be careful when drilling (sawing) a hole thru a vehicle roof, it is easy to
bend the metal leaving a dimple in the roof.
Have it done professionally or check with the shops that specialize in roof
antenna installations. I have heard of a Motorola tool designed for the
task.

Lamont with a dimpled roof (Greenlee Punch)

I need to address this, because Cecil has frequently declared all combinations of an ideal voltage source and resistor as a "Thevenin equivalent" as I see he's implied here once again. He has claimed this relieves him of the nagging problem of accounting for such things as power dissipation in a source resistance. I'll explain how this characterization and claim are false.

I often use an ideal voltage source in series with a resistance for illustration of transmission line phenomena. This very simple circuit allows complete analysis without the unnecessary clutter of more complicated circuits. You'll find this technique very widely used in elementary electrical circuits texts for the same reason, and well before the introduction of Thevenin or Norton equivalent circuits.

But these aren't Thevenin equivalent circuits. Let's review what a Thevenin equivalent is. I'll quote here from Pearson and Maler, _Introductory Circuit Analysis_, but you can find an equivalent definition in any elementary circuit analysis text.

"A theorem named after Leon Thevenin is often useful in reducing a complex circuit to a simpler one. This theorem, which is proved in Appendix E, may be stated as follows.

"Any one terminal pair (one port) network which is linear and which may have any number of independent and dependent transform sources (as long as the dependent sources are not functions of quantities outside the network) may be replaced by a transform voltage source in series with a transform impedance. The transform voltage source is the voltage across the terminal pair when these are open circuited and the transform impedance is the ratio of this transform voltage to the transform current which flows between these terminals when short circuited."

Pay particular attention to the first sentence of the quote. A Thevenin equivalent circuit is a reduction of a circuit to a simpler one. If you have a complex circuit containing multiple components and reduce it to a Thevenin equivalent, the theory says that the equivalent circuit looks just the same to the outside world as the original. Because the Thevenin equivalent could represent any number of very different original circuits, you can't determine anything at all about the internal workings of the original, such as power dissipation, by looking at the Thevenin equivalent. That's a completely valid statement which has frequently been misapplied.

A circuit consisting of a perfect voltage source and an impedance isn't a Thevenin equivalent circuit unless it's used to replace a more complex circuit. If it's used simply to represent those two circuit elements and none others, then all the conclusions we draw from the circuit, including dissipation in the source and impedance, are and must be valid. For that matter, the circuit analysis for a Thevenin equivalent must obey all rules and laws, including source and impedance voltage, current, and power. We only have to realize that any quantities within an equivalent circuit aren't necessarily the same as those of the circuit being replaced by the equivalent.

Declaring all circuits consisting of an ideal voltage or current source and impedance to be a Thevenin or Norton equivalent is wrong. Declaring that Thevenin or Norton equivalent circuits don't have to obey fundamental rules of circuit analysis is also wrong. Continuing to do so after more than ample evidence has been presented to the contrary is dishonest.

Roy Lewallen, W7EL

This is the conventional phraseology for describing the behaviour at
the impedance discontinuity.

Allow me to offer a specific example for which this phraseology is
inappropriate.

Consider a 50 V step function generator with an output impedance of
50 ohms driving a 50 ohm line that is 1 second long terminated in an
open circuit.

Turn on the generator. A 50 V step propagates down the line. The
generator is putting 50 J/s into the line. One second later it
reaches the open end and begins propagating backwards.
After two seconds it reaches the generator. The voltage at the
generator is now 100 V and no current is flowing from the
generator into the line. In the 2 seconds, the generator put
100 joules into the line which is now stored in the line.
The line is at a constant 100 V and the current is zero everywhere.

Computing Pf and Pr will yield 50 W forward and 50 W reflected.
And yet no current is flowing anywhere. The voltage on the line
is completely static.

And yet some will claim that 50 W is flowing forward and 50 W
is flowing backwards.

Does this seem like a reasonable claim for an open circuited
transmission line with constant voltage along its length and
no current anywhere?

I do not find it so.

> constructive interference at the non-standard output.

I presume by "interferometer example" you mean the experiment outlined on the following web page.

http://www.teachspin.com/instruments/moderni/experiments.shtml

Is there some mystery here? The explanation is very straightforward. No need for any philosophy, magic energy incantations, counter-balanced construction and destruction, or special short-lived created and immediately canceled waves. You can probably add as many of those elements as you like, but Occam says it isn't necessary, and they add nothing of substance.

Look carefully at the primary beam splitter in the center of the sketch. Suppose that the "standard output" is at a constructive maximum. Part of the light returning from MA1 is turned by the beam splitter toward the standard output. That light does not undergo any phase shift at the beam splitter, since in the configuration shown the reflection is internal at the "far side" of the beam splitter. Part of the light returning from MB1 travels directly through the beam splitter, and there is no phase shift. The two light beams are in phase as they leave the beam splitter heading toward the standard output. Constructive interference happens. (The mirror positions are adjusted as needed to achieve the maximum.)

What then happens to the portion of the light that heads back toward auxiliary beam splitter near the source? (Remember, these are beam *splitters*. I hope there is no question about why light might travel back toward the source.) In this case part of the light returning from MA1 travels directly through the primary beam splitter and it undergoes no phase shift. Part of the light from MB1 is turned by the beam splitter, and in this case there is a phase shift due to the external reflection. In general this phase shift would be around 180 degrees. As the web page points out, other shifts are possible, depending on the

exact details of the beam splitter. In any case, we now find two beams that are out of phase heading back toward the source. This of course leads to destructive interference and darkness.

Obviously everything shifts depending on the position of the mirrors and the length of the interferometer paths. As mirror MA1 is moved the standard output becomes dark while the auxiliary output becomes bright. I hope there is no question about that part.

As I said a day or so ago, there is nothing at all on this web page that is even remotely surprising or controversial. This is all very straightforward and well understood.

Is there something else you had in mind when you asked the question?

Well, whether you think so or not, you do say some pretty stupid
things. So if you're not saying the energy is in the canceled
reflected waves at the same time as it is in the forward waves, we're
still left to wonder at what time you think the energy *is* in the
canceled waves.
So far we haven't been able to pin you down on that.

It is unusual in an Australian made car mate, I bought a humble Holden Commodore (from the GM stable) near the bottom of the model stack, sort of an entry level car!
Car manufacturers get away with a lot over here, we are even the dumping ground for any vehicle that won't sell in Japan.

An antenna embedded in the windshield, which worked well--now that would be something!

My old buick had an active/amplified one--I would like to replace the one of this new buick with it (and I have no idea where the antenna is--perhaps it is the rear windows defroster!)

Why would you compute Pf and Pr when no DC current is
flowing? It is an invalid thing to do and unrelated to
reality.

> And yet some will claim that 50 W is flowing forward and 50 W
> is flowing backwards.

I know of no one who will claim that for static DC.
There are obviously no photons being emitted and
therefore, no waves.

Your example is unrelated to standing waves on an
RF transmission line where energy is in motion,
photons are continuously being emitted and absorbed,
and current and voltage loops are active.

One must realize the limitations of one's model.
The wave model obviously fails where there are no
waves.

What do you know? It narrows it to amateur radio,
the subject of this newsgroup.

To be entirely technically correct, since my assertion
was about average powers, the example transmission line
must be an integer multiple of 1/4 wavelength.

On the contrary, energy cannot be created or destroyed.
The "missing energy" from the destructive interference
at the standard output appears as constructive
interference at the non-standard output. Your assertion
above violates the conservation of energy principle.

> Suppose that the "standard output" is at a constructive maximum.

Contrary to what you say above, that cannot happen without
destructive interference occurring somewhere else. That
constructive maximum is going to exhibit more joules/sec
than the laser beam source. Where does the extra energy
come from?

Cecil,

I never said that energy could be created or destroyed. I never said anything about the requirements for balancing constructive and destructive interference. I never said anything about "missing energy". Those are simply your strawmen. They add absolutely nothing to the solution.

I believe my explanation is correct, and it made no use of those concepts of yours. I suspect you wanted me to stumble all over myself and end up sneaking in something about energy or constructive / destructive. Again, as I have said many times, those concepts are simply not needed beyond the realm of simple-minded hand-waving explanations.

If you want to critique my actual explanation, go right ahead. What did I say that was incorrect? Did I fail to account for all of the observables? I have no doubt that I failed to account for all of your strawmen, but that is your problem, not mine.

No, we are not left to wonder as I have explained
it many times. You are left to be a broken record
who refuses to solve the simple problem below.
If you solve it, you will no longer be able to
make the statement above and it seems that is
exactly the reason you refuse to solve it.

http://www.w5dxp.com/thinfilm.GIF

At t3, when the first internal reflection (0.009801w)
arrives back at the thin-film surface and interferes
with the external reflection (0.01w), what is the
resultant total reflected power?

If you solve that simple problem, you will know where
the energy in the canceled waves goes. Every time you
continue your silly broken record act, I am going to
challenge you to solve this simple problem.

That supposition is incorrect because it supposes that
the standard output can contain more energy than the
source is supplying. That supposition violates the
conservation of energy principle.

> ... those concepts are simply not needed ...

Of course, you could say that God can create energy
and destroy energy any time He choses. No other
concepts are needed.

I was unaware that all Amateur transmission lines
were a multiple of 1 wavelength long. Are you sure?

> To be entirely technically correct, since my assertion
> was about average powers, the example transmission line
> must be an integer multiple of 1/4 wavelength.

I would suggest 1/2 wavelength. For an intuitive proof,
consider a line with only forward power. Then think
of a quarter wave section with a voltage peak in the
middle. Then consider when the voltage 0 is in the
middle. Lots more energy in the former than the latter.
At 1/2 wavelength, the total energy in the line section
is constant.

Source record: 28815

Using a 259 is a big help for antenna builders, but before
using it one should know that the power supply does not
always break down the oxides formed at the circuit
connections, thus showing inconclusive results.
It takes at least 20 volts to breakdown the
oxides every time with confidence (and that includes silver).
So the use of a wallplug transformer with a 20 volt secondary
to create a spark across the coax connectiori will always
breakdown the oxides prior to using the 259.
Actually, it is always good form to always break down oxides
before using hand held measuring techniques which usually are
battery driven. This is the reason that reed switches are the
contacts of choice when using 12v computor driven circuitry,
since with gold plated contacts the underlying surface
often leaches thru the gold plating.
Have a happy day

This is a reasonable observation for a static situation where energy is stored on a transmission line.

If the example contained an ongoing consideration, like "Where does the power move to?", then it would be reasonable to consider that the wave continued to move, simply to avoid the complication of what EXACTLY happens when a wave starts and stops.

Don't know about a battery option. Art is saying we need 20V to breakover the oxide resistance. In my short stint as a component engineer years ago, our research showed that zinc coating could actually take as much as 35V to break over. Art is entirely correct on the oxide problem. Gold was very low breakover, however...we had not considered the substrate leaching into the gold (a very good point) but we considered the gold "flash" coating to be totally useless and in the 35V region because the gold flash is so thin it basically rubs off the first time it is used.

Yes, provided that you won't be exceeding its power rating.

> Also, comparing like losses to like losses, should it be 50
> ohm or 75 ohm and why?

Only the outside diameter is significant in determining the balun operation, and the only real effect that will have is in determining the number of turns and size you'll need to get effective balun operation. You should use the same impedance of coax as you use for feeding your Yagi, unless you intentionally want a mismatch for some reason.

Copper easily leaches into and alloys with gold, so when making a gold contact, the gold is never plated directly onto copper. A nickel barrier layer is virtually always used between the copper and gold to prevent this. When properly done, a gold contact will last a very long time. Gold is the only reliable way to do "dry circuit" (low voltage and current) switching, but a limited number of good connections can be made using other metals if sufficient contact pressure and wiping are employed.

Gold flash is much too thin to be a good contact material, as AI4QJ notes. It's sometimes used on switches designed for "hot circuit" operation, but not "dry circuit" switches. Its only purpose is to provide some protection of a base metal surface from corrosion until the first switch contact is made. After that, wiping and arcing are depended upon to keep the contact area clean.

If you rummage around in your junk box, you'll probably find miniature toggle switches rated 250 volts and others rated 20 volts. The former have silver contacts, for "hot circuit" switching. The latter have gold contacts for "dry circuit" switching. Some high quality switches have a good layer of gold (not "flash") over silver. Those can be used for either "hot" or "dry" circuit switching, but once used for hot circuit switching, the gold is rapidly eroded, so they can't later be used for dry circuits.

The design and application of electrical contacts is a discipline in itself. It's a much more complex and difficult problem than most people realize.

Roy,

I think you have misread the context, Suzy's application is a 1:4 balun for a 70cm Yagi, formed from a half wave balun to provide the phase inverted output of the balun.

She asked this question in another place five weeks or so ago, and my response was:

=== quote

If you have designed the dipole feed point to be 200 ohms so that the balun you describe transforms it to 50 ohms, the load on the half wave section is 100 ohms and it has a VSWR of 2:1 if it is 50 ohm coax.

The loss on the half wave section will be increased by the higher VSWR. The loss on a half wave of RG213 (Zo=50) at 432MHz with a 100 ohm load is 0.136dB, whereas it is 0.104dB for RG11 (Zo=75).

Does this say 75 ohm line is best. No, it says that RG11 is better than RG213.

You can explore these and other options with the loss calculator at http://www.vk1od.net/tl/tllc.php .

If you can't talk about it in numbers, do you really understand it?

Be ware of using low loss cables with foam dielectric for the balun...
check their minimum bending radius.

Don't depend on published velocity factor in cutting the balun, measure
vf and cut to tune the balun for the desired frequency.

===end quote

Apparently this is not regarded as a recommendation with explanation.

Roy, you may have a better turn of phrase.

>ohm or 75 ohm and why?

RG58 will do fine. Some constructors use small hardline such as UT141,
but mostly for mechanical convenience. At this wavelength, larger cables
are quite difficult to bend into the small loop this is required.

Since the balun loop is an electrical half-wave, any impedance will
reproduce the same voltage at the other end. (Minor details: cable loss
will have a small effect on voltage balance, but probably not enough to
be detectable; the optimum impedance for VSWR bandwidth would be 100
ohms, but that is unimportant because other parts of the yagi will
probably have a larger effect.)

In summary, choose whatever cable you can conveniently form into an
electrical half-wave loop.

Ian, I offered that solution elsewhere:

===quote
Obsessions about loss aside, try using the calculator to explore a halfwave
of UT141/RG405 semi rigid coax on a 100 ohm load. This is just 0.141" or
4mm diameter, and you need 245mm (as the calculator will tell you). It is a
quite neat solution to a half wave balun if you are not too obsessed about
0.0xdB of loss.
===equote

The loss for UT141 is 0.03dB worse than RG58C/U in this case.

Why would anyone make such a supposition that violates conservation of energy? I certainly did not. I merely said the output was at a maximum. Do you think that "maximum" is an illegal concept? Does "maximum" imply some specific numerical value?

Frankly, I have no idea what your objection is, and I have even less interest. I gave a standard textbook solution in a straightforward manner that gives the correct result, violates nothing, and is not complicated by all sorts of artificial constraints. If you want something more, have at it.

No, you didn't. Here's what you said:

> Suppose that the "standard output" is at a *constructive maximum*.

Now do you remember what you said? You implied that
constructive interference is present.

> Do you think that "maximum" is an illegal concept? Does "maximum" imply
> some specific numerical value?

Sorry, you did NOT say "maximum". You said "constructive
maximum".

A "constructive maximum" is greater than the average
output of the source, by definition. If you just said
"maximum", it would have been OK. When you added
"constructive" it means that, by definition, the output
is greater than the average source power.

I worked as a Snr controls engineer(yes I was a trained mechanical
engineer working outside my field) for 20 years at G.E

The bottom line in all contacts is pressure and wiping/scrubbing
action
GE won a suit against it and other wiring companies when the hoo haa
started over mixed aluminum wiring in house holds.
G.E. was dropped out of the cases when it was shown that clamping
pressure
prevented exposure of the contact surfaces. Actually silver contacts
even when normally closed will build an oxide between the contacts.
Because control devices are packaged incardboard boxes for shipment it
is nigh impossibble for the customer to get clean contacts because of
the sulphides exuding from the card board.

OK, remove the word "constructive" and simply leave "maximum". The same description still holds.

Feel better now?

Since you are reduced to nit-picking the exact choice of words, it appears you have nothing constructive to add (pun intended).

I gotta get one of the special dictionaries you have. The one that contains all of those "by definition" statements you like to use.

To facilitate learning about how the equations work and
what they may mean.

> It is an invalid thing to do

Not at all. The equations don't just stop working at 0 frequency.

In their general form F(t), there is no hint at all that F can
not be a constant. Or, if you prefer, a square wave with a width
several times longer than the length of the line.

> and unrelated to reality.

Anything unreal will also be unreal for the specific case of
sinusoids.

> I know of no one who will claim that for static DC.
> There are obviously no photons being emitted and
> therefore, no waves.

You really should try to stop thinking about photons
for just a short while. All the behaviours of a transmission
line can be understood and characterized without reference
to photons.

Analysis using classic circuit principles works quite fine
and has no difficulty at low frequencies.

> Your example is unrelated to standing waves on an
> RF transmission line where energy is in motion,
> photons are continuously being emitted and absorbed,
> and current and voltage loops are active.

There is no standing wave, but the example is quite
valid none-the-less. If you like, consider it as a
long pulse. And if you only want sinusoids, Fourier

will convert the pulse to sinusoids which you can,
using superposition, use to solve the problem.

The simplicity of the constant voltage makes it
easy to check your results.

> One must realize the limitations of one's model.
> The wave model obviously fails where there are no
> waves.

Think of it as a long pulse. That should satisfy your
need to have 'waves'.

So have you thought about "where does the power go?"

When the generator is matched to the line so that
the reflected wave does not encounter an impedance
discontinuity when it arrives back at the generator
(and therefore is not reflected), where does the
reflected power go?
Does it enter the generator?
Is it dissipated somewhere?

Answers to these questions will quickly lead to
doubts about the *reality* of "reflected power".

Yep, you guys would like to sweep the technical knowledge
from the field of optical physics and quantum electro-
dynamics under the rug. One wonders why.

> Think of it as a long pulse. That should satisfy your
> need to have 'waves'.

No, only photons will satisfy the definition of EM
waves. There are no photons. There are no waves. There
are no forward and reflected powers. There are no
changing E-fields or H-fields. There is not even any
movement of electrons associated with the source
voltage.

> discontinuity when it arrives back at the generator
> (and therefore is not reflected), ...

On the contrary, it is redistributed back toward
the load in the process of destructive interference
and becomes constructive interference associated
with the forward wave. Whether you call that a
reflection or not, the fact that the forward
power equals the source power plus the reflected
power tells us that reflected power being dissipated
in the source would violate the conservation of
energy principle.

> where does the reflected power go?

Power doesn't flow so
reflected power doesn't "go" anywhere. It is the
reflected energy that is flowing, i.e. going
somewhere. If the power were flowing, its
dimensions would be joules/sec/sec. Maybe
you would like to try to explain the physical
meaning of those dimensions?

> Does it enter the generator?

forward power = source power + reflected power

A component of the forward energy is equal in
magnitude to the reflected energy so no, it
doesn't enter the source.

> Is it dissipated somewhere?

Not during steady-state. During steady-state it
is being used for impedance transformation. After
steady-state, it is dissipated either in the
source or in the load as a traveling wave.

> Answers to these questions will quickly lead to
> doubts about the *reality* of "reflected power".

Reflected power is the Poynting vector associated
with the reflected wave. It exists at a point. It's
average magnitude (indirectly measured by a Bird) is

Re(ExH*)/2. It's direction is the direction of the
flow of reflected energy.

If you don't believe in reflected energy, let your
fingers become the circulator load resistor for
an open-circuit stub being driven by a KW source.

Yes, only the model I use substitutes a battery for the signal generator that you are using. The returning wave can recharge the battery, but how does the current stop? Or does it ever stop? From a practical aspect, the current must stop, but I can not explain how except by resistance that absorbs the circulating power.

We must keep the limitations of our models in mind.

The reflected wave that does not encounter an impedance at the generator must be on an infinitely long line, and therefore the conditions must have changed between the time of launch and return.

It makes more sense to think that the reflected voltage of (using your example) 50v meets 50v of forward voltage, and therefore finds an infinite resistance, coming to a stop.

If that happens, doesn't the same condition occur as soon as the reflected wave is first generated at the line end? The current really stops as soon as the end is reached, with the energy contained in the magnetic field converted to electric field energy visible as voltage. If this happened, the reflected wave could be better described as an electric "jump", similar to a hydraulic jump found in open channel flow of liquids, where kinetic energy is converted to potential energy.

This idea of an electric "jump" requires not a reflection occuring without a discontinuity, but a moving wave front that absorbs the traveling wave, bringing it to a stop (in this case).

Food for thought!

There is no such thing as DC! How's that you say? You have to turn it on sometime and someday you may turn it off. There for, DC is just very low frequency AC.

As another example of physics over thinking, I once had a physics professor describe in detail how an electric motor works using Quark physics. Very interesting but it has no practical value in using electric motors. Much like this long thread has nothing much to do with antennas.

"A better reason to avoid "stored" is that power isn`t stored at all, anywhere. Anyone who believes so should be able to tell us how many watts are stored in a 50 Ah, 12 volt battery."

The 50 Ah of energy stored in a battery may be withdrawn at a rate determined by the load, so it is a variable.

Velocity in a transmission line is a constant determined by constructtion of the line. Thus, energy stored in the line is determined by its length, voltage, current, and phase angle. These predict the rate of energy transfer (power).

That's false reasoning OM! Alternating current is not the same as discontinuous current. In the example you provide, a DC supply is either off or on; it does not reverse polarity! You do not make AC by switching on and off DC, even at 50 Hz (or your 60 Hz)

What type of coax and what is it going to be used for ?

Here is where I got 500 feet from a while back. Bury-flex. It might be
overkill for some applications, but I was using most of it on 50 mhz and up.

http://www.davisrf.com/ham1/coax.htm

Another place is :

http://thewireman.com/index.shtml

I usually pick up coax from him at the hamfests.

Ah is a unit of charge, not energy. The battery, making the simplifying (and invalid) assumption of constant voltage during discharge, contains 2.16 Mj of energy.

So the rate at which a transmission line transfers energy depends on its length? If I put 100 watts into a one wavelength cable and get 100 watts out, will I get 200 watts out if I extend the cable to two wavelengths?

But through the techniques of linear circuit analysis, we can split the pulsed DC into two components, a pure steady DC component and a symmetrical AC component. We can do two separate analyses with the two (AC and DC) excitations, and sum the results. The answer will be exactly the same as if we had done the calculations directly. One can then reasonably claim that the switched DC is the sum of an AC waveform and a pure DC component.

While it is probably not an issue for many, this and the lmr-400 has a center conductor that is aluminum covered in copper. I just like the 100% copper for the center conductor.

I don' t think the origional post was about a rotator on a tower, but the stranded seems to be the perferred coax for that. I did have some of the origional 9913 up with a rotator for about 10 years before I moved. It seemed ok, but I like the stranded center conductor and fully filled center dialectric.

For anything below 30 mhz and low power the rg-8x is ok. I am running some on 40 and 80 meters but with only 700 watts. This is just about the max for that coax , especially if sstv or rtty is being used .

A good grade of any of the rg-8 size has low enough loss below 30 mhz and the weather proffing is more of the issue.

My understanding is that the copper/aluminum issue is only a problem in the presence of oxygen and an electrolyte. A bond between the metals, which excludes these factors doesn't have galvanic corrosion problems. There's apparently a high-pressure crimping system which creates a cold weld between aluminum and copper wire which is considered permanent and corrosion-free. I suspect that for LMR-400 and similar cables, the copper layer is deposited on the aluminum via electrolysis.

LMR-400 is usually terminated to an N connector, using a pressure crimper to attach the center pin... soldering is also used sometimes. The recommended connectors come with heat-shrink tubing to seal the coax-to-connnector junction. When properly assembled, these connectors are moistureproof. The copper/aluminum junctions should thus be well sealed away from anything which would cause them to corrode.

LMR-400 does have another characteristic which some people feel make it unsuitable for certain applications - its foil-and-braid shield. It's nigh-on impossible to guarantee a good electrical bond to the foil itself, since it's aluminum and cannot be soldered easily... you have to depend on the pressure of the crimp, and on contact between the foil and the braid. People who build repeaters seem to consider this construction prone to become noisy over time.. Allegedly, current flow between the braid and shield can create micro-arcing and increases the transmitter's broadband-noise output, especially if the cable is moving e.g. due to wind hitting the tower. This can apparently result in enough broadband noise at the repeater's input frequency to cause desense problems or scratching sounds when the cable moves.

This doesn't seem to be a significant issue for simplex applications, though.

I have a 100 foot piece of Davis Bury-Flex I bought new and measured on a network analyzer. At around 200 MHz and above, it acts very strangely. The loss is 3 or more dB/100 feet above its spec. But if I take its natural two foot or so diameter coil and flex it a bit, the attenuation increases another couple of dB and stays there. When I check again some days later, I find that it's returned to its lower but still way out of spec value. It seems to be ok for HF, but I sure wouldn't use it above 2 meters. The genuine LMR400 I have is within its spec and doesn't exhibit this strange behavior when flexing.

That is interisting. I bought 500 feet and cut it into 4 lengths from about
120 to 140 feet each. They were then rolled into coils about 2 or 3 feet in
diameter. Two of them had pl 259 plugs on them and the other two had N
connectors installed. I did not use any high teck equipment, just about 100
watts at 440 mhz, a bird wattmeter, and a good dummy load. The losses in
each piece was within the specificiations of the coax. The same meter was
moved from one end to the other to see how much power was lost.
This was done mainly to see if the connectors were installed correctly as
it would have been difficult to change it out after the antennas were
installed.
It has been up almost a year. Wish I could pull it down and recheck it to
see if it was acting up.

I am a RACES / ARES member who is trying to actually prepare for deployment with the ability to carry on effective communications from anywhere. I'm here in the antenna forum to get advice on a portable antenna system. I'm not here to join anyones particular theoretical antenna behavior cult. If you have real world experience with a portable multi band antenna system that actually worked for you please share that experience with me.

Ive seen a couple of folded dipole antennas advertised that appear to have some sort of fifty ohm dummy load at the center of the fold. Do those things do more then provide a heat source for fleeing birds?

There are several compact vertical and horizontal antennas being sold complete with stands or tripods are any of them worth their freight?

The so called spiderweb beams look interesting can anyone offer real world experience on those?

I'm honestly looking for advice that is based on experience rather than a particular theory of what should work. I want to know what does work from real world users.

Tom;

A friend of mine had a multi band dipole sometime ago. This ant had a separate dipole for each band all connected to one balun. It took us all afternoon to tune it for optimum operation. Each time we tuned one dipole the others needed work. YMMV.

I have a B&W folded dipole all frequency folded dipole that does what I want it to do. When operated in NVIS I was able to contact stations over 400 miles away. I most likely could have done better but that was all I need for the application.

The connection at the ends of the dipole consisted of a non inductive resistor of either 600 or 1200 ohms (I disremember which). This does swamp the reflected energy when the wire is non resonant. There are those who claim the antenna is the work of the devil and those who sing the praises of the thing. All I can say is that it did the job I wanted it for. My problem now is I can't string it up at my new QTH. Lot to short and no place for the sky hooks. :^(

I also have a screwdriver antenna on my vehicle that also does the job it's designed for. It is not the most efficient antenna in the world either. However, I learned long ago that whatever answers the question

no matter how inefficient is a success.

Screwdriver's can be mounted on a tripod and will perform.

Dave WD9BDZ

Remember YMMV

Tom,

Used to provide checkpoint communications for the Baja offroad races.
Best antennas we found for consistent regional communications were low
horizontal dipoles fed with balanced line. You could tune them on any
band and the radiation pattern was UP. Google NVIS antennas, or start
here:

Roy Lewallen wrote:
"Ah is a unit of charge, not energy."

The most common 12-volt battery is the lead-acid storage battery used in automobiles. It should not be allowed to become completely discharged nor to remain less than fully charged for a long time. The battery`s capacity is rated in amperes x hours. The discharge rate is assumed to be 8 hours. Slower discharges can be supported for more ampere-hours and faster discharges likely won`t meet the rated ampere-hour product.

A 50 Ah battery would be expected to deliver about 6.25 A for a period of 8 hours provided its electrolyte does not rise to more than 110 degrees F. 2-volt cells can be discharged down to 1.75 volts per cell or a voltage of 10.5 volts for the 6 cells of a 12-volt battery.

Roy Lewallen wrote:
"So the rate at which a transmission line transfers energy depends on its length?"

No, it depends on the power fed into the line.

Storage in the line depends on its length, plus the incident and reflected energies per unit length of the line. Velocity is fixed by construction of the line so a slow velocity factor allows more energy storage as the source energy output is constant and independent of the line`s velocity factor.

And yet all the circuit theory derivations of reflection
coefficient, power, voltage and current distributions
work just fine for DC (or, if you prefer, low rate pulses).

Digital designers use exactly that for solving real world
problems. They do not refuse to solve problems when the
conditions approach DC. The equations all work.

An intriguing accusation. Transmission lines can be
understood well, and real world problems solved without
reference to photons and EM waves. Just use the well
known circuit theory based equations. And they extend
all the way to DC.

For those who like EM waves and photons... Why do you
want to limit yourselves? Why won't you use the circuit
theory bases equations to solve problems for which they
work? Just because EM waves and photons do not?

Unfortunately, this is quite wrong. And I continue to
be surprised that you argue that there is a reflection
where there is not an impedance discontinuity.

Some parts of the rest of your post are correct by
coincidence, but since the underlying premise of
reflections where there is no discontinuity is
incorrect, I have snipped it.

But this debate has been had before. You do not want
to understand how the output impedance of a generator
affects a returning signal. I have offerred references
and you have refused to look. I have offerred spice
simulations, and you have refused to look. When the
discussion moves to simpler generators so that the
behaviour can be studied, you will declare them
uninteresting because they do not represent "real
ham transmitters". You will make jokes about 10 cent
resistors, not realizing that is how real test
equipment prevents re-reflection. (How well would
a TDR work, if any substantial amount of the return
was reflected?)

When you decide that you do not want to argue that
reflections occur where there is no impedance
discontinuity, and are willing to study output
immpedance, the learning can begin.

If that were true, we would not be having this
argument. The real world problem is - where does
the reflected EM energy go? Since you have not "solved
that real world problem", your methods are suspect.

OTOH, optical physicists solved that same problem
long before any of us were born.

> Why won't you use the circuit
> theory bases equations to solve problems for which they
> work?

The main reason not to use your methods is that you use
them to arrive at wrong concepts. EM waves cannot exist
without energy. If there exists no EM wave energy, there
are no EM waves. If EM waves exist, they are necessarily
associated with energy and momentum, both of which must
be conserved. The amount of that energy flowing past a
measurement point/plane in a unit-time is the power
(density) associated with the reflected wave. Even the
energy and momentum of a single photon can be calculated.

Any length of transmission line with reflections contains
exactly the amount of energy necessary to support the
forward and reflected waves. That amount of energy exists
in the transmission line and is not delivered to the load
during steady-state.

Because your model doesn't tell you where the reflected
energy goes, you assume there is zero energy in reflected
waves. Again, I challenge you to use your fingers to
replace the reflected power circulator load in a system
with a KW source driving an open-circuit. That shock therapy
will, no doubt, change your mind about the non-existence of
reflected power.

> be surprised that you argue that there is a reflection
> where there is not an impedance discontinuity.

Since an absence of reflections violates the conservation
of energy principle, there is something wrong with your
assertion and your earlier example was proved to contain
a contradiction.

Psource = Pfor - Pref = Pload

Pfor = Psource + Pref = Pload + Pref

Those equations are true only if reflected energy
does not flow back into the source. I suspect that,
contrary to your assertions, the actual real-world
source presents an infinite impedance to reflected
waves.

> When you decide that you do not want to argue that
> reflections occur where there is no impedance
> discontinuity, ...

You simply fail to recognize the impedance
discontinuity.

Please perform the following experiment to prove
there is no impedance discontinuity and no distortion
and get back to us.

zero ohm
TV RCVR--+--TV source--+--Z0 stub----------open
|
Z0 source impedance resistor
|
GND

The source output goes into the stub. Reflections
occur at the open end of the stub and flow back
through the zero impedance source to be dissipated
in the Z0 source resistor and displayed without
distortion on the TV RCVR. If what you say is true,
it should be duck soup for you to prove.

There are a multitude of answers for this question.

I know my solution will annoy the purists, but I offer it anyway...
I would recommend using the SGC-237 tuner (not cheap)! If it cannot
load what ever antenna you can get up or improvise it probably cannot
be done. With this device, a ground and 28 feet of vertical wire you
can work to 160 meters. Of course the better the ground, the better
the performance. A quarter wave on frequency might work better, but
whatever you have will work.

If the conditions permit a more elaborate antenna, the SGC-237 will
make the matching an non issue.

I am aware that a pi-network and skilled operator can out perform the
tuner but the tuner takes the problem out of the field and into the
planning stage.

"(How well would a TDR worh, if any substantial amount of return was reflected?)"

A properly terminated line does not make reflections. I would imagine multiple reflections on an oscilloscope produce the same smear as as they do on TV.

TDR is suggested for monitoring bridge integrity and performance. Where was it when we needed it? TDRs are likely cheaper than replacing all the questionable bridges.

TDR is used to determine the characteristics of electrical lines by observing reflected waveforms.Tektronnix is a leader with its "I Connect" software. Roy can likely describe it. Agilent suggests TDR is the most general approach to evaluating the time domain response of any electromagnetic system is to solve Maxwell`s equations in the time domain. The foregoing is courtesy of Wikipedia. The incoherent structure of the last sentence was theirs too.

Supports are an open question. I expect to have at least a forty eight foot, two inch, aluminum, mast to use because that is what I'm buying to support a directional or omni antenna array for the six, two, and three quarter meter bands. That mast is available in eight foot long sections. The six sections, couplers, guy rings, and the rest of the mast assembly will live in one of those long air luggage carriers with two built in wheels on one end that people use for things like skis. I can certainly include one or more of the surplus GI plastic or aluminum masts in the mobile equipment set, but three masts would be too much for deployments involving commercial airline flights. Depending on how heavy all of that is I could put one or two of the forty one foot Jackite(r) poles or equivalent in that same kit.

The power would be the one hundred watts that can be gotten from one of the DC to daylight mobile transceivers such as my Yaesu FT-857D. I expect to build my lugable station into an air transport case with the internal shelves and the removable front and back covers. That station will have 1200/9600 packet for Winlink 2000 radio Email composed of a laptop, TNC, and data radio. A dual bander for VHF / UHF voice and the Yaesu FT-857D for HF. If the Kenwood TM-D710A continues to get high reviews I'll use it for both voice and data on VHF / UHF and leave the separate TNC for a ground mobile deployment. The rest of the weight will be the power supply and rechargeable AGM battery up to the weight limit prescribed for a single piece of airline passenger baggage. If that ends up being impractical from a weight standpoint I might break it up into two air transport cases. If I remember correctly they simply won't transport an overweight item but they just charge you extra for having an extra piece of baggage.

My reason for wanting to identify the antennas first is that they sort of govern what else is possible.

I didn't mention the issue of antenna tuners it but I was thinking of including the Yaesu FC-30 tuner in the HF set but I wanted to get some advice first. I was considering that tuner because it can be directly controlled by the transceiver and even bolted right to it. If that's a bad idea I have not bought one yet.

I take it you are not a fan of the diesel fuel and ammonium nitrate fertilizer solution to stumps. {;<)

As far as Autotuners, especially the Motorola based, Stepped, Binary,
Lumped, Incremental Component Tuners, (SEA, SGC, etc) they have some
inherent problems that are a function of the design criteria. First,
they can't tune ANYWHERE (50 Khz or more) near the natural 1/2 wave
point of the attached antenna, where impedances head for infinity.
Second, they MUST have a very good RF Ground to work against, in order
to function properly. Don't even "think" the word "Counterpoise", but do
demand the phrase, LOW Impedance RF Ground, when engineering an
effective use of such an Autotuner. There have been some, that have used
these type tuners, as a Tuned Element in the center of a Dipole, but
again, these are severely compromised antenna systems, and not likely to
out preform a Dipole or Inverted Vee, Tuned for the Operating Frequency.

Hi Tom,

With some care in isolating the VHF antennas you hoist aloft, you
could turn the mast and guys into a thick radiator capable of covering
80 through 30 Meters omni. With some effort in trap building (into
the conducting guys) you could extend that higher. The more radial
guys, the easier the broad band match; however, this can become an
issue of diminishing returns and increasing complexity.

I've had good luck with a portable antenna system that I use QRP with an FT817, on 80-10m. I use a High Sierra Sidekick short screwdriver antenna (other "shorter" brands would also work) with a modified BuddiPole mast and tripod. WIth my 5 watts I can work many stations that I can hear as long as there are no pileups - if so you need some patience!

I modified this by making a bracket for the mast that holds 4 , 10-12 ft MFJ telescoping antennas horizonatally to form the counterpoise. I use a 10 ft telescoping antenna on the screwdriver to make it more efficient on HF. All of this fits in a medium suitcase and when folded is only 24 inches long. To power the screwdriver motor I use a 9 volt, yes 9 volt, standard battery with a manual up/down switch. I use multiple Mix 31 ferrite beads on the coax and antenna motor wires at the antenna. I prefer the screwdriver type antenna as it is remotely tunable and most of them work well on 9-12 volts and don't require heavy duty batteries - I like to switch bands a lot but don't like to manually tune antennas "every 10 minutes". This setup puts the base of the antenna 7 to 8 feet above the ground so you have a bit less ground loss than if you put the ground counterpoise on the ground or a few feet above the ground.

The angle of radiation on this is probably at the horizon so if you're looking for short range HF then this would not be the configuration to use.

I've thought about making the bracket commerically available if anyone was interested, to augment my mobile antenna supplies (www.repDesign.us). If interested let me know.

No, you would like people to believe what you say
is true about what I want to believe even though
it is false. I am not stupid enough to believe
the same energy can be in two places at once. What
I believe is that water can be in a pipeline
from beginning to end. I believe the same thing
is true for energy. Steady-state conditions in
a transmission line are a continuous energy pipeline,
not a snapshot in time.

Please solve that simple problem so we can discuss
your answer. When the external reflected wave of
0.01 watts encounters the internal reflected wave
of 0.009801 watts at t3, what is the total reflected
power toward the load between t3 and t4. If you solve
that simple problem any confusion about "what I want
to believe" will be lifted.

Roger Sparks wrote:
"It is not too hard to use the concept of traveling waves to derive the familiar reflection coefficient to SWR relationship."

Yes. Terman has done it for us in his 1955 opus. He just uses the letter S to represent SWR.

On page 86:
"The voltage and current of the incident wave at the load must satisfy Eq. (4-8) =
Eprime / Iprime = Zo."

And at the top of page 86:
"The reflected wave.----is identical with the incident wave except that it is traveling toward the generator. Eq. (4-11) =
Edouble prime / Idouble prime = -Zo."

"The load voltage is the sum of the voltages of the incident and reflected waves at the load,....
The load current is the sum of the currents of the incident and reflected waves at the load,....
The vector ratio EL / IL must equal the load impedance ZL."

"The vector ratio E2 / E1 of the voltage of the reflected wave to the voltage of the incident wave at the load is termed the reflection coefficient of the load.

Reflection coefficient = rho = E2/E1 =
(ZL/Zo)-1 / (ZL/Zo)+1."

And on page 97:
"Standing-wave ratio = S = Emax/Emin, Eq.(4-20)
And: S= [E1] + [E2] / [E1] - [E2], Eq. (4-21)"

The standing-wave ratio S is one means of expressing the magnitude of the reflection coefficient; the exact relation between the two is S = 1+[rho] / 1- [rho]

or [rho] = S-1 / S +1
This relationship is illustrated graphically in Fig. 4-9.

Best regards, Richard Harrrison, KB5WZI

Are you willing to use a printed circuit board? If so, a directional coupler is pretty easy to make, microstrip style. You can even use a knife to score the copper and then peel away the unwanted copper. It's common to have one through-line and two coupled lines, one for "forward" and one for "reverse" measurements. You terminate each coupled line with Z0 (50 ohms, commonly) at one end and put a diode rectifier (or other power measuring device) at the other end. Although it's probably easiest to get a pretty good 50 ohm termination at 450MHz using surface mount parts, you can do OK with a couple 1/4 watt metal-film axial resistors. If you used 1206 size surface mount resistors, you should be able to solder them down with a decent standard iron -- they aren't all that small.

If you really can't find any construction articles on making one, maybe I could put something together and post it somewhere. They're far easier to make than many people seem to think.

Cheers,
Tom

I didn't take it as a joke any more than I would take as a joke the concept of holes moving in a semiconductor. One is the speed of the absence of negative charge, the other is the speed of the absence of photons, both of which are valid parameters that could be measured. But nothing moves transversly in a standing wave which is what we were speaking of.. When you encounter a standing wave, it is appropriate to suggest "Don't just do something, stand there!". That, to me, is a joke. :-)

Dear Group:
The embedding of antenna in the windshield (windscreen) must go back to
before 1982. I am sure that I had a student thesis on the topic before
1982. As I recall, the designs worked quite well. The student's
experimental antennas were embedded (expensive) until someone allowed a
bunch to fall over and shatter. Then the student found that the same
measured results were obtained by placing the antenna against and outside of
the windshield. Heck, in the real old days antennas were sometimes run
under the car.

I don't suppose this will have much of an impact on you, but power doesn't 'interfere with other power', Cecil. (Physicists have known that since before you were born.) They know that fields interfere - voltages superpose. As I explained before, the equations you're using are correct shortcuts. They are NOT physical analogs of the phenomena.

http://www.w5dxp.com/thinfilm.GIF

I worked problems similar to yours with Walt Maxwell about two years ago. In fact I talked with you about it here on the newsgroup. You haven't really done this one correctly, but I do like the picture. You claim to know that power doesn't reflect, yet you insist on showing power reflecting, and canceling and doing all sorts of presumptuous things in your drawing. Furthermore you neither indicate nor do you consider whether the laser continues to irradiate the front surface at t3. Which, if it does, would make your number at t3 obviously incorrect.

It is apparent that you hope your answer and your correspondents answer are not the same. Without going further, I'll concede (happily) that my answer would not be the same as yours. For one thing I wouldn't express the answer in units of watts. And of course the solution cannot have energy flowing in the form of canceled waves. The only energy flowing is in the form of waves which do not cancel.

Electromagnetism isn't just like water - even though water conservation is also very important. :-)

If at some point you decide to discuss an RF problem of this type using transmission lines and voltages, we might be able to arrive at the correct solution using a more tenable process. But it might only come out the way you want if we do it your way. :-)

> For one
>thing I wouldn't express the answer in units of watts.

Hi Jim,

Once again, I will align with Cecil - even though he previously took me to task for doing exactly what he does in his gif file, namely add/subtract power, watts, what-have-you. I have long ago discarded his contrarian responses with a smile noting this long tradition of Cecil impeaching his own data.

However, returning to the division/substitution/addition/subtraction of power, watts, what-have-you; the power (explicit and implicit) of light has a long-standing tradition in science. For whoever's purpose, a simple correlative has long been observed that the sun's irradiance upon a square meter of earth, on the solstice, at noon, on the equator, through the atmosphere is ~1000 Watts.

That is, there are 1000 Watts available IFF you can extract it, or harness it. The solar power conversion industry has built a market on this one characteristic.

It thus follows there is some percentage that is not available due to any number of mechanisms, reflection being principle among them. So, it follows an interface will refract some portion and reflect some portion. Cecil would variously demand this be expressed in energy when he was losing the power rhetoric, or demanding it be expressed in power when he was losing the energy rhetoric. We can all agree that rhetoric is "powering the debate" not the science.

The "proof" of his non-glare glass is a museum piece of mathematics that bears no relationship to actual life - but that is fine and well; unfortunately it also failed in the purity of mathematics where you take him to task for:
>Furthermore you neither indicate
>nor do you consider whether the laser continues to irradiate the front
>surface at t3. Which, if it does, would make your number at t3
>obviously incorrect.
So much of Cecil's "proofs" accumulate their proof through Retro Cognition - which is performed rather sloppily.

So, I see no problem, at the conceptual level, of working with portions of power within the context of illustrating an argument; and I am not even sure it matters in the long run, but then this has never

run the full course to test that "matter."

And I didn't say that powers interfere with other powers.
I said the external wave interferes with the internal
reflected wave. Waves certainly do interfere. The watt
values are the respective irradiances of the two waves.
Here's a quote from my years old "Worldradio" article.

"Likewise, the EM fields in the waves do the interfering.
Powers, treated as scalars, are incapable of interference."

As you well know, I have been on record for a number of
years saying powers are incapable of interference.

I do wish you would stop bearing false witness about
what I have said. You will never win the argument
using unethical tactics.

> You
> claim to know that power doesn't reflect, yet you insist on showing
> power reflecting, ...

Sorry, you are confused. I do not show power reflecting. I
show waves reflecting with the Poynting vectors as indicated.

Exactly how do you explain your refusal to work through
this simple problem?

> It is apparent that you hope your answer and your correspondents answer
> are not the same. Without going further, I'll concede (happily) that my
> answer would not be the same as yours.

Then one of us would be wrong but you will never win the
argument by refusing to solve the problem. Richard C.
attempted it in the past and, through power superposition,
came to the conclusion that the reflections would be
brighter than the surface of the sun. Hopefully, your
solution would not be the same as his.

> For one thing I wouldn't express the answer in units of watts.

Sorry, Irradiance is in watts/unit-area. Since the laser
beam is considered to be of constant area, the units of
watts simply indicate the power in the laser beam area
quite like watts indicate the power in a transmission
line of constant area.

Please point out where I added or subtracted power in that
diagram. I don't see an addition or subtraction of any kind.
In fact, the last time I offered this example, you were the
one who superposed powers, not I.

The ultimate impeachment of one's own work. How I could be called upon to testify for or against it is amusing however, and goes to how rhetoric is what the game is all about. But it is still vastly more amusing by the challenge to skip the rhetoric and simply drill a hole in his own work:
1 WATT applied at t1
yields
0.99 WATT transmitted
0.01 WATT reflected

To the casual observer with normal powers of sight (and by Cecil's frequent admission, he is not listed among those numbers):
1 = 0.99 - -0.01
some time later, t3 we find 0.009801 WATT added (in the same direction as the reflected) t2 component. The number, of course, is wrong, but even more wrong is it being the product/quotient/sum/difference of any physical operation. This, will reveal in an admission from Cecil about his being human, prone to errors, and being especially human that it proves he was right.

To the casual observe having once observed the normal linear math applied at t1, and repeated at t2, that it would be a novel experience to discover that Physics had shifted such that at t3 the additive/subtractive associations once exhibited at t1 and t2 had been replaced by -um- something else (Cecil's Universal Law of Whatever?).

Discarding the obvious math error, the logical error follows that the point was that 0.01 - 0.009981 was structured to prove something (sorry "Whatever") through phase? All vectors are labeled with POWER and there is no suggestion of DOT or CROSS products being intended. So now human error has compounded across math and logic.

Discarding the math and logical error, that is all fine and well as any further examination at any other interface yields the same linear addition/subtraction directly expressed within the graphic (it would take a clown to insist that the operators were missing when the vectors are so evident).

Discarding these errors changes nothing as it takes very little mathematical skill to observe the failure of the "anti-reflective"

glass. At t1 0.01 WATT is reflected and with ALL subsequent internal reflections the TOTAL power available to cancellation is found in the reflection at t2 (0.0099 WATT) which is obviously less. The sum of all those internal reflections could never exceed what is available - and what is available is less than the first reflection:
0.01 WATT > 0.0099 WATT

I am, as already expressed to Jim, quite content to treat interfaces as power splitters. Hardly remarkable stuff and yet I suspect some will trounce me and it will be heartily amusing coming from Cecil - so I dare to plunge myself into this abyss ;-)

Convert the powers to ergs, dynes, sheckles, or any other metric, and the imbalance still defeats the proposition of total elimination. Arbitrage traders make billions of Euros in the stock market with less margin.... except for one fellow in Paris who must have been following Cecil's theories of conservation.

As the prophet Douglas Adams once wrote
"any event that is infinitely improbable will,
by definition, occur almost immediately"

That's why it takes so little effort to demolish Cecil's logic.

Richard, to muddy up this discussion of adding powers one might insist that we define which "power" we are talking about. Is is peak power, RMS power, PEP power, average power, 5% THD power? Is it real power or reactive power? For arithmetic functions like addition and subtraction, all we can do is superimpose waves of E and/or M. In doing do, we are performing an additive property of fields which can only imply a squared function on power which is a scalar and not a vector with an arrow tip at one end. I see where you are coming from, i.e. that power can sort of conceptually be dealt with this way but some sections of the derivations have been skipped, that is, the important sections transforming the arithmetically added/subtracted waves and converting them (by geometric 'squared' function) to power of no vector direction and only a positive, scalar value (the square of any wave is positive). Power cannot be negative nor can it be directional. EM waves can. This is not an example of what I think you might consider to be my normal nitpicking. Powers cannot be treated like this. I know you yourself are trying to make a concession here but I think it will not work in this case due to the scalar nature of power; it just isn't that flexible a property for you to allow that. True, if my stereo puts out 100W of 5% THD power per channel, I can say that my 2 channel stereo is 200W 5%THD. My friends will

understand. But that is not what we are dealing with on the non-reflective coating examples where power is attempted to by vectored, added/subtracted in various directions etc..

Sure power can be negative or be directional. Power is the time rate of energy movement or use. If energy is moving up at some rate, the direction of power is up. If energy is moving to the left, the direction of power is to the left. And in a transmission line, where energy can move in either of two directions, we must define one direction as being positive. Power representing energy moving in the other direction is negative. Power is the product of v(t) and i(t), both of which can be positive or negative, so the product can be positive or negative. Without the constrictions of a transmission line, power is more generally E X H, where E, H, and E X H are all vectors with a magnitude and direction.

Run the little TLVis1 program and look at demo 4. Notice that the power trace goes both above and below the center line. Energy movement to the right is defined there as positive, so negative power represents energy movement to the left. If power couldn't be negative, it wouldn't be possible for the average power to be zero. But the average power calculated at any point along a transmission line terminated in a short,

open, or pure reactance is zero at all times in steady state, while the instantaneous power alternates between positive and negative.

It's absolutely essential to get a grasp of some of these very fundamental concepts and units before tackling problems such as reflections or energy movement.

Reflectance = 0.01, Transmittance = (1 - 0.01) = 0.99
Reflectance + Transmittance = 1.0. This is really basic
optical physics 201.

> some time later, t3 we find 0.009801 WATT added (in the same direction
> as the reflected) t2 component. The number, of course, is wrong, ...

We can ignore the rest of your posting until you prove this
assertion. The indexes of refraction were carefully chosen
to obtain a Reflectance (R) at each boundary of 0.01. The
Transmittance (T) is therefore 0.99. Please prove that the
0.009801 watt value is wrong.

first internal reflection = (((1w*T)*R)*T) = 0.009801w

The terms in the irradiance equation are in watts/unit-area,
i.e. power density. What I have done is multiply both sides
of the irradiance equation by the area of the laser beam
which is assumed to be ideally constant. Thus the power
densities are converted to powers.

If you remember, that's what we started with. But
there are too many rugs inside a transmission line
under which the technical truth can be swept. With
a laser beam, there is nowhere to hide the truth.

One elementary thing we need to get straight about
voltages is when destructive interference or
constructive interference is occurring. If two
coherent voltages traveling in the same direction
in a transmission line are superposed in the same
Z0 environment, is there destructive interference,
constructive interference, or no interference.
Here are three simple examples:

1. V1 = 100v at 0 deg., V2 = 100v at 45 deg.

2. V1 = 100v at 0 deg., V2 = 100v at 135 deg.

3. V1 = 100v at 0 deg., V2 = 100v at 90 deg.

If (V1+V2)^2 > (V1^2 + V2^2), then constructive
If (V1+V2)^2 < (V1^2 + V2^2), then destructive
If (V1+V2)^2 = (V1^2 + V2^2), then no interference

RE: Stumps....
I try to resist the urge to experiment in that direction. I continue
to look for a mentor that has gray hair, and a complete inventory of
eyes & limbs. I sure miss the days when every hardware store carried
Calcium Carbide.

Can you recommend any fuses or detonators?

RE: tuners
I like built in tuners but I like having the tuner at the antenna even
better. In days past a big mismatch was just an inconvenience. Today
RF at the operating position means the only equipment that does work
is the radio.

I use only two HF antennas at this time. The 28 foot vertical with the
SGC-237 which works fine 10-160m with no Shack RF and A Cushcraft A3S
40-10 beam with the tuner in the TenTec Jupiter. Both meet my
expectations.

A vertical MAY NOT meet your mission profile for short range
communications. A low dipole (High enough not to present a safety
hazard) may be more useful.

As an earlier poster pointed out, it would be best to select a length
that is NOT a half wave on a desired operating frequency.

Once again, a clever technician can beat any tuner but I find it
difficult to be clever when it is dark, cold, wet and hungry.

100% absolute nonsense. You express light intensity in terms of
watts, completely neglect the incoming beam in your calculation,
completely ignore the fact that 'power' doesn't phase cancel, and then
claim that the most valid approach isn't as good. Unbelievable.

What do you get when you multiply both sides of the
irradiance equation by a constant unit-area? I get watts.

> completely neglect the incoming beam in your calculation, ...

Now there's some magic invisible beam that exists only
in your mind? Please explain.

> completely ignore the fact that 'power' doesn't phase cancel, ...

The phase cancellation angle in the irradiance equation
is between E-fields, not between powers, so your objection
is just a straw man. When the two interfering waves are
180 degrees out of phase, the total irradiance diminishes.
I'm surprised you don't know that fact of physics.

> and then claim that the most valid approach isn't as good.

Both approaches are equally valid but one wonders why a
laser beam in air is so objectionable that you absolutely
refuse to perform a simple calculation. Guess I will have
to do it for you. The power density of the external reflection
is 0.01 watts/unit-area. The E-field of the internal reflection
undergoes a 180 degree phase shift and the power density is
0.009801 watts/unit-area.

http://www.w5dxp.com/thinfilm.GIF

Multiplying the irradiance equation by a constant
unit-area yields:

Ptot = P1 + P2 - 2*SQRT(P1*P2)

Ptot = 0.01 + 0.009801 - 2*SQRT(0.01*0.009801)

Ptot = 0.019801 - 0.0198 = 0.000001 watts

The total reflected power from t3 to t5 is one microwatt.

What happens to the rest of the energy? It is redistributed in the opposite direction as constructive interference. It is a continuous steady-state process that continues until the laser is shut off.

Don't let the surface mount parts intimidate you. Its not that
difficult especially when you are doing just a few componets. I must
admit that I had a heck of a headache after building a little
microphone preamp. I glue the part I am going to install to a
toothpick to give me something to hold it with.

Cecil,

Why do you feel so compelled to worry about the precise definitions of constructive and destructive? They don't help with a numerical solution to any problem. Can't we simply survive with the ordinary everyday meaning of these qualitative terms, various Popular Science style websites notwithstanding.

As I pointed out some time ago, more advanced treatments such as Born and Wolf "Principles of Optics" or Jackson "Classical Electrodynamics" don't use these qualitative terms at all.

As a side note, if you want to see what your pal Hecht thinks of Born and Wolf, take a look at

http://www.aip.org/pt/vol-53/iss-10/p77a.html

What a hoot! I gave you that and MORE and you still come up short.
This is like demanding the bank to correct their repossession notice
because you want them to acknowledge you owe them more. ;-)

The infinite summation from 0.0099 WATT available internal reflections
will NEVER exceed 0.0099 WATT and
0.01 WATT > 0.0099 WATT
remains true throughout all time.

To repeat the obvious, your argument of total elimination has been
debunked.

Thanks very much Tom. Yes I'm certainly OK with PCBs and I was aware of the
basic circuitry. But I felt that the stripline would have to be special in
some way for the 435 MHz that I need. Perhaps a special length?

From the mathematical perspective, we are dealing with conservative fields that have polarities. This is where the concept of "vectors" resides. Basically the arrowhead of the vector points towards a positive polarity of a boundary that is negative on one side and positive on the other.

Power is not a conservative field, neither is energy. It is not a field at all. Furthermore, there does not exist in absolute terms either negative energy or negative power UNLESS you decide to venture into the newer fields of exotic physics to which I believe you refer to as "poltergiests". You can assign relative "polarities" to power if you which to to talk about more power or less power but you can never superimpose or cancel power of different polarities.
There is no -12 watts heat to cancel out +12 watts heat. Heat is heat
You can take 0 watts heat over time and average it out to +12 watts if you also have +24 watts with time but nothing is cancelled out. For superposition and cancellation, you must reduce down to the components of power (voltage and current).

You can speak about positive power moving along a transmission line in terms of distance. Yes it does move over distance, but not as a vector. It is carried by the fields which *are* vector quanities. Power is merely an expression that is always positive because it is a squared quantity although it may be multiplied by SQRT(-1) when defined as a reactive term. The following terms are valid: Assuming power is integer N,

P = N watts
P = jN watts

The following terms are not valid:

P = -N watts
P = -jN watts

Sorry, I disagree.

I wasn't speaking of power moving anywhere. Energy is moving on a transmission line, and the power at any point on that transmission line is v(t) * i(t). v(t) and i(t) are sine functions in steady state, so the power at any point (except where v or i is always zero) changes sign four times during each cycle of v or i. There is no "reactive term" in v(t) * i(t). It's a simple time domain quantity.

Movement isn't required in order for quantity to have a direction. One of many examples is a static magnetic field, which most certainly has a direction but no movement.

If power can never be negative, please explain how the average power at any point can equal zero on an open circuited line. The average power at any point is the integral of v(t) * i(t) evaluated over one cycle of v or i and divided by the period. In steady state, v(t) * i(t), as I calculate it, is a sinusoid with twice the period of v or i, and centered around zero. Because it's centered around zero, its average is zero. This has been shown mathematically and quantitatively a number of times on this group.

It's no wonder that people are having so much trouble understanding energy movement, and why it's so easy to lead them astray with red herrings and pseudo-science, when there's so much misunderstanding about the underlying concepts and terminology. If you start with concepts which are fundamentally erroneous, the knowledge you build on them is bound to be wrong.

The point is you neglect to indicate and consider all the assumptions
you've made in arriving at your answer. Try solving the problem for
any thickness other than an odd multiple of 1/4 wavelengths - try .39
lambda for example. Then tell us about how reliable your 'let's
assume power interferes' method is.

>> completely neglect the incoming beam in your calculation, ...
>
>
> Now there's some magic invisible beam that exists only
> in your mind? Please explain.

Not much is known about it. The only indication shown in the picture
is "1 watt laser". Unless it is only producing light for the time it
takes light to travel a half wavelength, it continues to irradiate the
first surface at t3, producing additional reflected light which
superposes with "from 1st internal reflection". And there is also the
transmitted portion which sums with the internally reflected light at
t4. And so on....

>> completely ignore the fact that 'power' doesn't phase cancel, ...

The efield does not have units of watts/"unit-area". In fact neither
does anything else, to be precise.

First rule of creative bookkeeping: You can do anything you want as
the numbers come out right.

> The sum of
> all those internal reflections could never exceed what is available -
> and what is available is less than the first reflection:
> 0.01 WATT > 0.0099 WATT

The sum of the internal reflections must always equal the energy from
the source that has neither been reflected from the front surface nor
transmitted to the load up to that time.

> constructive and destructive? They don't help with a numerical solution
> to any problem.

Of course they do, Gene. That is the whole reason for presenting them. Being able to spot the destructive interference and the necessary equal amount of constructive interference explains a host of the problems presented here which are a lot like the problems faced by optical physicists over the past couple of centuries - which they have already solved for us. Optical physicists know exactly where all of the energy goes because they were forced to deal with power densities, something that a lot of hams have yet to learn to deal with.

Setting aside the cause of interference, the results of interference explains in simple terms why a Z0-match with a reflection coefficient of 0.5 can manage to eliminate 100% of the reflections. When we tune our antenna systems for a Z0-match to 50 ohms, we are causing *total destructive interference* toward the source as defined by Hecht in "Optics".

Here's an example:

```
100w
XMTR--50 ohm line--+--1/2WL 300 ohm line---50 ohm load
Pfor1=100w-->|-->Pfor2=???
Pref1=0w<--|<--Pref2=???
```

What are the magnitudes of Pfor2 and Pref2? Hint: no need to resort to voltages and currents. Optical physicists couldn't measure voltage and current in light and yet they did just fine. The above power values in a transmission line are very much like irradiance (intensity) in optical physics. Why not avail ourselves of that free knowledge even if only for reasons of *knowledge for knowledge's sake*?

> remains true throughout all time.

Obviously false as any textbook will attest. All reflections
toward the source are eventually eliminated thus forcing all
the energy to wind up flowing into the glass. And you really
missed badly on what happens in the thin-film.

The *forward power* within the thin-film is *1.010101 watts*
during steady-state. The *reflected power* in the thin-film is
0.010101 watts during steady-state. Such is the nature of
total destructive interference at the air to thin-film surface.

Your strange assertions are exactly why hams need to learn
this readily available knowledge from the field of optical
physics. It remains to be seen whether the "experts" will
side with you or with me or choose to remain silent.

I've said it 100 times - power doesn't interfere. You
are hoping to win by innuendo and falsification what you
cannot win with a rational ethical argument.

> The efield does not have units of watts/"unit-area".

I didn't say it did. The units being used are the number
of degrees of phase angle between one E-field and another.
You are hoping to win by innuendo what you cannot win with
an ethical argument.

You have not disproved anything I have said. You have just
set up straw men of your own design and knocked them down.
When you stop your unethical tactics I will resume the
discussion.

Thanks for that. I really want to emulate a throughline (like the Bird 43 I
once had) and am thinking more in the terms of a stripline on PCB (using
BNC), with parallel lines to sniff the RF and diodes to convert for the
meters. But what I'm usure of is the sort of dimensions I should use for 70
cms, and wther these are critical. How long should the stripline be, what
spacing and so on, so that it doesn't in itself introduce errors and
misleading results. The sort of thing I would imagine would be in the ARRL
handbook, but I want to avoid the expense of buying the book if it's not in
there at all. BTW, most of the designs I've seen are HF or for up to 2
meters at the highest. I specifically want 70 cms, 435 MHz to be exact.

I have a Micronta SWR/POWER METER speced for 440 MHz.
I suspect it uses a small ferrite core rated for 440 MHz
for the current pickup and a capacitive divider for
voltage. Seems all you need is a ferrite core rated
up to 440 MHz and you would be in business. Seems to
me that even a ferrite core not rated for 440 MHz
could be used and calibrated on a one to one basis.

The stripline (microstrip, really, if it's on one side with
groundplane on the other, which is the easiest to do) can be almost
any length. It will have zero coupling if it's an electrical halfwave
or integral multiple of a halfwave, but otherwise, it will work. It
will have the maximum coupling if it's an electrical quarter wave
long, and the change in coupling versus frequency is minimum at that
length, but it's usable even if it is very short. I'm using one

that's about half an inch long down as low as 1MHz; the directionality is fine, and the coupling is simply very small. You can use the free-to-download RFSim99 program to get a microstrip design for a particular coupling, but what the program doesn't tell you is that the coupling they list is for a coupler an electrical quarter wave long. To a pretty close approximation, the coupling will go as the sine of the electrical length, so for example if you use the design for a 20dB coupler but make it only 1/8 wave long, the response will be about sin(45 degrees) or .707 times as much, or 3dB lower: it will be about a 23dB coupler at that length. That means the coupled port power will be 23dB lower than the input power, so if you had 10 watts going in, the coupled port would receive about 0.05 watts, which is 1.6V rms. That likely is a bit more than you need to drive a diode detector. There can be some advantage to keeping the voltage low enough, if you're using a diode detector, so that the detector is in the "square law" region: DC output _voltage_ is proportional to RF input _power_. On normal FR4 board stock 1/16" thick, leaving one side as a ground plane, a pair of traces 1/8" wide, separated by a 1/8" space, will give you about a 25dB coupler and pretty close to 50 ohms. It does depend on the particular dielectric constant of your FR4 substrate, which varies from manufacturer to manufacturer and by particular material type. In that microstrip environment, the wavelength of 450MHz signals will be on the order of 40cm, or about 4 inches for 1/4 wavelength, so you can see that your coupler doesn't have to be very long, physically.

If you don't mind working with SMA connectors, you can get SMA jacks that mount directly on the edge of a 1/16" thick PC board, and that makes it very easy to make a connectorized version of a coupler. You can get SMA-to-BNC (or to other series) adapters--mpja.com have them at reasonable prices, for example--to get to other environments.

If I wanted a coupler for a power/SWR meter for 450MHz, and assuming I was going to use Schottky diode detectors, I'd first think about the range of powers I wanted to handle, then select a coupling to give me perhaps 0.2V RMS at max power at the coupled port. If space permitted, I'd make the coupler an electrical quarter wave long, since its sensitivity would then be least affected by frequency (the very flat top of the sine curve). I'd use a DVM to read out the detected DC voltage (and make sure my DVM or digital panel meter or whatever wasn't affected by the 450MHz signal directly!). A 200mV full-scale 3.5 digit meter would then cover to very low SWR at full scale, and to fairly low power. The one other thing I'd want to do is insure that the meter--the directional coupler part, specifically--was optimized to 50 ohms, which would require a known good 50 ohm (assuming I wanted it to be 50 ohms) load to test. Likely I'd make some pretty accurate measurements of the board substrate thickness and relative dielectric constant before starting, so I got the trace widths and spacings right from the start. It's possible to trim the coupler up in impedance by carefully narrowing the traces, and down by adding a grounded plane above the board--adjusting the spacing to trim the impedance. Be

aware that each of those will also change the coupling slightly,
however.

Hope that helps some!

Cheers,
Tom

Cecil,

I don't claim to be an expert, but since you called me a "guru" I will
respond.

I would never attempt to solve this problem in such a clumsy manner. As
Jim pointed out, your bouncing wave lattice technique might work when
the phase of the moon is correct, but otherwise it is useless.

All that is necessary is to set up the standard wave equations, apply
the appropriate material parameters and boundary conditions, and voila!,
the answer is there. No muss, no fuss, no worries about the exact
definition of "constructive". Many textbooks show exactly how to do this.

Thanks very much, Roy. It was probably my mistake, using the word "Orthogonal" when quadrature would probably have worked better.

Can you explain your last sentence? Why does this happen?

I have been following these threads with some interest, and I very much appreciate your analysis, as it adds greatly to my understanding. Thank you very much for taking the time to write so clearly.

There is one point I still have trouble with. The concept of power flowing in standing waves where the superposition goes to zero, and yet the energy flow is unaffected and continues in opposite directions on either side of the null point.

Anyway, I have googled until my fingers get sore, and I haven't found a good explanation of why this happens. Everyone says it is well understood from basic undergraduate theory, but the only references I can find are from graduate studies in Quantum Electrodynamics. This is not much help.

So I have to form some image in my mind of why these waves do not interact. Here is a partial picture:

1. Electromagnetic waves travel at the speed of light in whatever medium they are in. For them to interact, there must be some advance information they are about to collide. But that would require transferring information faster than the speed of light, which is

forbidden.

2. The fields in electromagnetic waves are at right angles to the direction of propagation. There is no longitudinal component, and therefore the waves have no advance warning they are about to collide. There is no vector component that is common to both that would allow any interaction, so there is no way this can happen.

3. Photons carry no charge. They are not deflected by electrostatic or electromagnetic fields, and do not interact with other photons. Electromagnetic waves are made up of photons. Since photons do not interact, EM waves also do not interact with each other.

The above concepts seem to make sense, and allow me to get some sleep at night. Can you tell me if they are valid, and if there are other ways of explaining this phenomenon?

Mike Monett

Your long, pointless answer demonstrates exactly what I said. (Oops, I guess there was a point after all.) With the possible exception of the extremes of completely in-phase or completely out of phase, the terms constructive and destructive are qualitative and of little value for numerical calculations. Your previous message, the target of my response above, noted precise limits for the transition from destructive to constructive, as if it were important.

I am curious about one thing, however. You make frequent comments about the long history of "optical physicists". Do you know any "optical physicists"? Have you read any books on the history of "optical physicists"? Have you ever been employed as an "optical physicist"? Is there some particular reason why you feel the need to lecture me about "optical physicists"? I have about 40 years experience as a genuine physicist working in the field of optics, although I am not sure if that makes me an "optical physicist". I don't believe I have ever heard the terminology before you started throwing it around.

OK, lets change the string. Now it's the top guy wire for a 1/4 wave vertical at 560KHz. When you pluck it, you can hear it pinging as the waves are reflected. Maybe it would be difficult to take that to a symphony performance, but hey, true art is art no matter where you find it:)

If you make the coupling line very short wrt wavelength, you can analyse it with a lumped constant approximation.

You can think of the coupled line as located in the electric field of the main line, and it will have a voltage difference to ground.

Similarly, the coupled line will be cut by magnetic flux due the the current in the main line, and so a voltage will be induced end to end in the coupled line.

By adjusting the resistor at one end of the coupled line, you adjust the contibution of these current and voltage derived samples, and can adjust them so balance each other (ie no meter deflection) when V/I on the main line is 50.

When the coupled line is short, the characteristic impedance of the coupled line is not very critical.

You should be able to achieve sufficient sensitivity for 5W pwr on 70cm with 20mm of coupled line.

The Zo of the though line is more important, it is the main determinant of the insertion VSWR of the instrument, so you need to strive to achieve close to the desired Zo, presumably 50 ohms.

Next, don't put the coupled line to close as it will load the main line and degrade the insertion VSWR.

Then adjust the R at the end of the coupled line to null the DC output on a 50 ohm load.

Repeat for the other coupled line (if you use one).

Check for symmetry, ie that reversing the instrument gives exactly the same readings on the dummy load.

Tom suggested Schottky diodes. Dick Smith has 1N5711 Shottky diodes (at exhorbitant prices), or you could get 1N34 germainium diodes from Jaycar.

BTW, you did mention the Bird 43, the above is not frequency compensated like the Bird slugs, deflection will be frequency dependent.

Owen

The following quote sounds like an interaction of photons to me.

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit
constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

I suspect that coherent photons can interact at an impedance
discontinuity which causes reflections.

That's a false statement. In the field of "Optics" as presented
by Hecht, they are entirely quantitative. In addition, when an
amateur radio antenna system is matched it is indeed completely
in-phase. Thus the concepts work well for the most common
condition in amateur radio, i.e. a matched system.

> Have you read any books on the history of "optical physicists"?

Of course I have. "The History of Modern Science" is a good one.
Another is "The Great Physicists from Galileo to Einstein".
How many centuries has that irradiance equation been around?
You know, the one that you have yet to understand.

>
> Can you explain your last sentence? Why does this happen?

The "non-zero" was unnecessary, and a result of a too-quick evaluation of an equation, although the meaning of Z0 at DC isn't clear anyway.

There are at least two related ways to show that a medium can't have a purely imaginary Z0 (more correctly, intrinsic impedance). One is to use the telegrapher's equation for a transmission line immersed in the medium:

Z0 = sqrt((R + jwL)/(G + jwC)) (w = omega, the rotational frequency)

For Z0 to be purely imaginary, the quantity under the radical has to be purely real and negative. A little algebraic manipulation shows that this requires that RG + w^2LC < 0. All the quantities are positive, so it can't happen.

You can also use

Zc = sqrt(mu/ceps) where ceps = the complex permittivity, mu = the permeability of the medium, and Zc the intrinsic impedance.

The complex permittivity ceps = eps - j*sigma/w

where eps = the real (DC) permittivity
sigma = the conductivity of the material

You end up with the same situation, where for Zc to be purely imaginary, the quantity under the radical has to be purely real and negative, which requires that mu * eps < 0. Remember that mu and eps here are the actual permeability and permittivity, not the relative values we often use.

A little further research reveals that there are some fairly recently created man-made materials which have a negative permeability. Those could presumably have a purely imaginary intrinsic impedance, provided that they have a positive permittivity. So there might be an exception

to my statement, although it isn't something you're likely to encounter
for some time to come.

Please exclude me from the "everyone" in "everyone says". I don't say
that power flows, period. We've seen the serious traps people have
fallen into by making this assumption and trying to build from it.
That's why you won't find it in texts.

You don't need a reason for them to not interact, you need a reason for
them to do so. In a linear medium, there is none.

I'm glad they work for you. I'll have to leave it to others to comment on their validity, since I don't buy into the notion of flowing power in the first place.

A common 1/4 stick fire cracker as the detonator and model rocket engine
nichrome wire igniters wired to energize from a safe distance away. You
have to pack the mixture pretty tight with the fire cracker in the
middle. Wrap the nichrome igniter wire around the firecracker's fuse,
run your wire out a safe distance, connect wires to battery terminal and
key operated switch / covered push button combination, make the needed
safety announcement, when all check points report all clear insert and
operate the keyed switch, begin countdown, press button.

Owen's comments reminded me that I always used to think of coupled-line hybrids as sampling the magnetic and electric fields at a point, and of course you can adjust the ratio by adjusting the load as he suggests. But then something began nagging me: his example of a 20mm (2cm) line isn't exactly short compared with a "full length" quarter wave coupled line. Because of the relatively slow propagation in stripline over FR4 PC board material, a quarter wave is only about 10 cm for 450MHz signals. But thinking of it in terms of a distributed line system, you're just terminating the coupled line in the proper impedance to not get reflections off that end; so this same thing works even with full 1/4 wave lines to adjust the directivity.

However, if you have one through line and one coupled line, and you've made them very symmetric so you can swap the two and not see a difference, then if you have to terminate the coupled line in other than 50 ohms to get perfect directivity (no reflection from that port), it also says that the through line is not 50 ohms. As Owen points out, you'd really like that through line to look like 50 ohms (or other system Z0 if you wish), so it doesn't disturb the system it's installed in. There's the incentive to make the coupler symmetrical and tuned so the coupled line terminates properly in 50 ohms, to get best directivity.

I'll readily admit that the details of coupled lines from a fields perspective is a bit beyond my full understanding, so there may be an error in my thinking about this, but I believe it's pretty accurate. The thing that comes first to my mind is that for stripline, the propagation velocity for even and odd modes is different, but still, I think if the lines are lightly coupled, the paragraphs I wrote above are a valid way to look at the situation.

Geez, Schottky diodes should be dirt cheap these days. It's germanium that are hard to find around here, unless they are old stock.

Cheers,
Tom

1670. Balun vs reactance

Hi to all..

How does a 4:1 or 1:1 balun affects reactance? For example, what would be the new value Z=a +/-Jb of, say, Z=3000 - J4500 Ohms after transformation by the 4:1 or 1:1 balun ?

Thanks de Pierre VE2PID

Depends upon the design of the balun and needs to be
measured under operating conditions. That's one reason
a lot of us prefer 1:1 chokes. *If* the choking impedance
is high enough, it will perform the balun function.

What I do with impedances like 3000-j4500, with a 16.4:1
SWR on the 600 ohm open-wire line, is to extend the
feedline until that impedance is transformed to
600/16.4 = 36.6+j0 ohms and install my 1:1 choke at
that current maximum point. Here's how I do that.

Hi Tom.

First things first - Are you willing to learn anything? This isn't as rude as it may first appear. I've had a good bit of experience with folks in emergency ops who don't want to learn about HF, they just want a one size fits all answer.

>
> Ive seen a couple of folded dipole antennas advertised that appear to
> have some sort of fifty ohm dummy load at the center of the fold. Do
> those things do more then provide a heat source for fleeing birds?

They are not particularly good antennas. But they might just be good for your purpose. They are very wideband, and that may be important if you don't want to run a tuner. Many of their limitations can be overcome with applying more power.

Before I get beat up by the antenna purists, the folded dipoles do serve a purpose of being antennas that you don't have to mess around with. I'd never own one, but for this purpose, maybe so.

> There are several compact vertical and horizontal antennas being sold
> complete with stands or tripods are any of them worth their freight?

I suspect that the folded dipole would work a bit better.

> The so called spiderweb beams look interesting can anyone offer real
> world experience on those?

No experience here, but under emergency condx, it seems like a nuisance.

> I'm honestly looking for advice that is based on experience rather than
> a particular theory of what should work. I want to know what does work
> from real world users.

And yet you came here! Just a joke son...

a few questions might be in order:

Are you looking for rapid setup, or are you going to be in a regular location with the antenna already in position? You noted deployment, so I'll assume the former.

For speed of deployment and flexibility, it is hard to beat a general purpose dipole, ladder line, and a tuner.

It is inexpensive, inherently all HF band, and performs pretty darn well. You do have to run a tuner, which is pretty simple, but that goes along with my how much do you want to learn schtick.

All you need is a couple of trees, or even masts, and you can be set up and running in a short time.

Length of the antenna can be adjusted according to how much space you have at deployment. Of course, the shorter you make it, the less well it performs on the lower bands.

I've used these for years, and have talked and buzzed the world over.

I tend to shy away from beams for emergency use, unless I have an omni or near omni antenna to complement them.

The much maligned Folded dipole would be next on my list. Simple to set up and use. It isn't as forgiving on length as the general purpose dipole however.

Those shorty verticals work pretty fair on the higher frequencies, but are a real b***h on 80 meters. The bandwidth is quite sharp, and can give you fits.

I use a bugcatcher on 80 in the car because there isn't much alternative, and I have to have multiple taps to tune 80/75 meters.

Screwdrivers tune more easily on 80/75, but their performance is down a little from the bugcatcher. I'd steer away from short verticals if you think you're going to be doing work in that neighborhood.

Hope this helps.

There is nothing inherently sub par in performance for a windshield mounted antenna. I wouldn't doubt that potential performance can be better, since you can get more length in the area that no one is going to put up with in a fender mount antenna.

I guess we'll never find out the speed of dark then!

That's another quip. Lambaste it if you wish. 8^)

On a more serious note, perhaps some people with the courage of their
convictions would say, place their hands in that "dark spot"?

100 percent cancellation should equal no energy at that point, so it
should be perfectly safe.

I'd like to thank all you kind fellows for your assistance, but unfortunately a lot of it is rather above my head. I need to be pointed at an article that spells out exactly what dimensions, how to build etc. (eg is there one in the ARRL handbook?) And Owen, no in this case Suzy if not short for Susan, so I'm not the person you knew.

OK, back to the first posting I made here. How about if I build one,
test it, and post the design and results somewhere? As I noted in one
of my postings, if I were to make one, I'd first consider how much
power I wanted to read, full scale, so if my offer is appealing, let
me know how much power you want to measure, max. Don't tell me a
kilowatt if you really are going to use it at 10 watts, because if I
design for a kilowatt, 10 watts will be low enough that you won't be
able to read it very well. In fact, I'd propose 10 watts as a
reasonable full scale for a lot of ham uses.

Cheers,
Tom

Here's the thing about all this that you don't appear to understand. Whenever waves occupy the same space, their amplitudes superpose.* It doesn't matter whether they're traveling different directions or the same direction; at the given point in time and space their amplitudes superpose. It doesn't matter if they happen to be at the same frequency or at different frequencies; their amplitudes superpose. It doesn't matter that names have been given for particular special cases of superposition. It is still the same phenomenon. Whether the waves sum to zero when they're equal in amplitude and out of phase, or double when they're equal and in phase; whether they're traveling the same direction or not, it's exactly the same phenomenon in any case you might cite. It's simply the superposition of waves. The particular end result isn't what determines the type of phenomena involved.

In no case do the fields from one wave affect the fields of another wave. Only matter can have an effect on waves. Waves do not reflect, bounce, refract, or diffract other waves. Only matter can do those things. You should to believe Maxwell's equations if you don't want to believe me.

ac6xg

*There are exceptions of course. The waves must exhibit the same kind of behavior in order to superpose. Sound waves do not superpose with

radio waves for example.

> a 23dB coupler at that length.

Actually, the sine approximation isn't all that good. Since it's not
been easy for me to find on the web and others may have similar
trouble finding it, I'll reproduce a better equation here:

coupling = (Zeven-Zodd)*sin(theta) / [2*Z0*cos(theta) + j*(Zeven
+Zodd)*sin(theta)]

where:
Zeven and Zodd are the even-mode and odd-mode impedances of the
coupled line pair:
Zeven is the impedance seen when testing one line of the pair,
when both lines are driven by the same voltage.
Zodd is the impedance seen when testing one line of the pair,
when the two lines are driven by equal-amplitude but 180
degree out of phase voltages.
Z0 = sqrt(Zeven*Zodd)
theta = electrical length of the coupled line section

To find the coupling in dB, just take 20*log10(coupling).

You can get the even and odd mode impedances from a program like altc,
available at http://altc.sourceforge.net/. You may also be able to
find formulas that give them to you for common structures like
stripline and microstrip just from the dimensions and relative
dielectric constant of the substrate.

In the hopes this may be valuable info for one or more of the
lurkers...

Cheers,
Tom

> what determines the type of phenomena involved.

I agree with everything you said up until the last sentence.
The end result is exactly the clue that tells us what
happened.

Waves can superpose with or without interference.

Waves can interfere with or without wave cancellation.

Wave cancellation cannot occur except at an impedance
discontinuity (a change in mediums). Given that, wave
cancellation indeed involves one wave's effect on the
other wave. What is it about "redistribution of energy"
that you don't understand?

> In no case do the fields from one wave affect the fields of another
> wave.

There are certainly cases where that statement is true.
But there are many cases where the statement is false.

How can wave cancellation occur without the waves affecting
one another? Here are a couple of quotations from Ramo and
Whinnery: "... the reflections from the front and back
surfaces exactly cancel under these conditions. ... reflections
may be eliminated by canceling the reflected wave from one
slab by that from another placed a proper distance from it."

Yours is a false statement according to these two references.
Please contact Melles-Groit and Florida State University.

http://www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and
the thickness of the film are such that a phase difference
exists between reflections of p, then reflected wavefronts
interfere destructively, and overall reflected intensity is
a minimum. If the two reflections are of equal amplitude,
then this amplitude (and hence intensity) minimum will be
zero." (Referring to 1/4 wavelength thin films.)

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity
will appear as enhanced intensity in the transmitted beam.
The sum of the reflected and transmitted beam intensities is

always equal to the incident intensity. This important fact
has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit
constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

Using Dielectric Beamsplitters to find the "missing energy"
in destructive interference

Are you saying the two waves engaging in total destructive
interference have no effect on each other?

Hi Tom

That's a kind offer, but you needn't go to all the trouble of building it.
Just a pointer at the practical design will do (but no complex theory --
over my head!).

I want to investigate various 70 cm antennas (central frequency in Australia
435 MHz). TX is switchable 5 10 20 watts. I want to standardise on BNC, and
have readouts on analogue meters (probably 1 mA movements)

The fact that a superposition of waves results in a null, either in
certain regions, or everywhere does not mean that one wave had an
effect on another.

> What is it about "redistribution of energy"
> that you don't understand?

Not a thing. We're just attempting to clear up a couple things that
you misunderstand about it.

Actually, I don't see any reason why sound and radio waves can't be superposed. Superposition means that we can solve the problem separately with either one and get the same answer as we do if we solve it for the combination. That would be true of sound and radio waves -- we get the same sound whether or not the radio wave is present, and vice versa.

An exception to superposition is when the medium isn't linear, such as, for example, typical ferromagnetic materials. In that case you get a different result when solving for each component if the other is there or absent, so superposition doesn't hold. Also, of course, some quantities, such as power in a lossy medium, can't be superposed because the sum of the individually calculated results isn't equal to the result calculated from the sum of individual components.

Well, it's certainly a simple matter to superpose graphical
representations of the amplitude and phase of any two (or more) waves.
It's just that I'm not sure what kind of unit conversion to make in
order to superpose longitudinal sound pressure waves in SPL units and
transverse electromagnetic waves in volts per meter in any meaningful
way. ;-)

Thanks,

If as a mere beginner (and female to boot) I may butt in here, surely a sound wave is a totally dissimilar thing to a radio wave. A sound wave is an air pressure wave (it does not propagate in a vacuum)and is in no way comparable to a radio wave, which is electromagnetic and does. I don't believe the two interact in any way.

You're absolutely correct. Superposition requires that the two don't
interact.

"Superpose" shouldn't really be used to describe waves, even though I've
admittedly been guilty of misusing it myself. Superposition doesn't
represent any physical property, characteristic, or interaction at all.
So two waves which "superpose" do nothing. Superposition is only an
analytical technique, and the way we do an analysis has no effect on the
physical reality. It's a shortcut we can use to simplify complex
problems. When the requirements(*) are met, we can solve a complex
problem by turning on one excitation at a time, solving the problem as
though that excitation was the only one present, and adding the
responses we get from the individual excitations. This is often easier
than having all the excitations on at once and solving for the total
response. When superposition applies, we get exactly the same result by
either method. So two waves don't "superpose" -- they do what they do
regardless of the analytical technique we use. But we can solve some
problems by applying superposition.

(*) If y1 is the response to excitation x1 (y1 = f(x1)), and
y2 is the response to excitation x2 (y2 = f(x2)), then
Superposition can be used if y1 + y2 = f(x1 + x2).
In other words, the sum of the responses to individual excitations has
to be the same as the response to the sum of the individual excitations.

I do. One cannoy superpose a vibtation of air molecules with a vibration of alectromagnetic fields. Each is independent of the other. Independent phenomena cannot be superposed.

>Superposition means that we can solve the problem separately

Only if the situation involves 2 or more waves upon which the silution is dependent.

> with either one and get the same answer as we do if we solve it for the

Deiagree. Superposition obviously requires that the final output wave is dependent upon the 2 or more input waves.
>
> An exception to superposition is when the medium isn't linear, such as,

A non-linear medium simply changes the shape of the contributing waveforms, usually dissipated into heat that is easily accounted for and not related to the superposition.

> quantities, such as power in a lossy medium, can't be superposed because

You have seen the light! Thank you Roy.

Finally you admit that power cannot be superposed. It can be reflected and it can interact but not in the same way that vectored "waves" in a conservative or non-conservative field can interact.

TRUTH?

The quote you respond to harbors some correct statements, but only
some and already hedged by the OP with qualification. If we are to
discard qualification and elevate supposition to truth, TRUTH becomes
cheaper by the pound.

Radio waves and sound DO interact. The question is by degree, and at
what frequency. Of course, it does require that you know what sound
is, and what radiation (RF) is. The OP has already demurred, but Dan,
you are always quick to pick up the banner and wave it. This can only
make you a target of course. BANG!

Hi!
Anyone had any experience with a G5RV which is NOT symetrical relative to ground?
Mine is on a sloping section and varies from 3.2 metres AGL at the western end to 7.5 metres at the Eastern. Although I get a reasonable match with a single coil Z match tuner I have reason to believe that there is quite a large electrical imbalance in the system, notably in the poor rejection of local noise signals.
I came across a Z match circuit on optushome.com.au by VK3YSF which has a 25 pF variable capacitor from one side of the open wire feeder to ground. However the article gives no further information about this component except to call it a "Balance" capacitor.
Has anyone else come across this problem? If so was it a question of "cut and try" or is there a proper technical approach one can use?
Hoping for some "feedback".

Sure they interact Richard. The gravitons that bind the air molecules to the
space time continuum, along with the galactic particles levitated by Art's
160m antenna interact with the RF photons in accordance with the unified
field theory.

>Of course, it does require that you know what sound

Only on the rare occasions that I recognize truth.

> This can only
> make you a target of course. BANG!

I will await you guitar string standing wave antenna that couples 20KHz kinetic vibration energy with 20KHz RF. But you say it depends on frequency and of course the RF and sound wavelengths are too dissimilar here. At which frequency might they interact, given that the velocity of RF is 3 X 10E8 m/sec and the velocity of sound is 4 x 10E2 m/sec? particularly, as the OP indicated, in a vacuum?

BANG (800 Hz)!

Then we are not using the same definition for "interference".
I am using Hecht's definition for "interference" quoting:
"Optical interference corresponds to the interaction of two
or more light waves yielding a resultant irradiance that
deviates from the sum of the component irradiances. ...
Interference effects occur when two or more coherent waves
overlap. If two coherent waves of the same amplitude are
superposed, *total destructive interference* (cancellation,
or in the case of light, darkness) occurs when the waves are
180 degrees out of phase. *total constructive interference*
(reinforcement, or in the case of light, brightness) occurs
when they are in-phase." emphasis is Hecht's, not mine.

"Cancellation of two coherent waves" sure sounds like they
have an effect on each other.

> The fact that a superposition of waves results in a null, either in
> certain regions, or everywhere does not mean that one wave had an effect
> on another.

Sometimes it does and sometimes it doesn't. If the waves
disappear from existence, they had an effect on each other.
If they don't disappear, they had no effect on each other.

Wow, what a lack of misunderstanding!

Of course anyone can assign a relative sign in front of a power quantity. For example, it might be convenient to assign a minus sing to reflected power to distinguish it from forward power. But in no way does assigning a minus sign as a means to signify "reflected power" also mean that the power is "negative". It simply means positive power moving in the negative direction! This as opposed to negative voltage which truly is negative with respect to an absolute reference point of earth ground.

Here is a simple question: Real power = I**2/R

How can real power be negative?

I assume you will not tell me to use negative resistance or jI.

How can the energy in the power ever be negative? I assume you will not tell me to consider negative time.

Give me ONE example of how real power expressed this way can EVER be negative. Every time you give me a v(t)*i(t) and assign a sign to indicate direction of current flow -i(t), I will ask you to calculate i(t)**2/R and tell you to make that a negative number.

This is straight from EE101.

Tell me how to make I**2/R a negative number that generates negative heat
and which is not fundamentally erroneous.

Yes, thuis truly is fundamental. I am rather surprized at this diatribe and
how it exposed *your* lack of understanding of fundamental concepts.

Hi Dan,

And yet you validate this perception by your own response. I don't
agree with it, but lacking others' replies, you set the standard.

The simple observation here is that you supplied a response that does
not reveal what sound is - taking such phenomenon as sound for granted
frequently attends a lack of definition. Sound, like light, arrives
through our senses such that we take them for granted and assign them
very limited characteristics based on perception. Everyone believes
in what they see and hear, and as it is a personal experience, it must
be TRUE!

It takes very little effort to show otherwise, and this is often
followed by outrage and denial; again, because of the personal
attachment.

Now why would it do that?

>But you say it depends on frequency
>and of course the RF and sound wavelengths are too dissimilar here.

Similarity of wavelength scale is immaterial. Sound wavelength can be shorter, longer, or the same size as radiation wavelengths; but your first have to know the what sound is. Even RF changes wavelength entering into dielectrics or waveguides.

Radiation passing into a dielectric can engender sound, which in turn can engender radiation emerging from the dielectric. Wavelength may come to bare on problems of distance within it, but this is not an issue of radiation nor sound, but rather material.

>At which
>frequency might they interact, given that the velocity of RF is 3 X 10E8
>m/sec and the velocity of sound is 4 x 10E2 m/sec? particularly, as the OP
>indicated, in a vacuum?

A guitar string in a vacuum may not transmit sound through the vacuum, but sound is why the string vibrates. Application of radiation is perfectly capable of setting the string into vibration (but you still don't know by what frequency or by what degree).

You first have to be able to distinguish what sound is to relate it to radiation (RF is one way, but not the only way of expressing it).

The correlation is extremely common - but largely immaterial to the topics of discussion typically encountered here.

No, negative power means that *energy* is moving in the direction we've declared to be negative. This follows directly from the definition of power as the time derivative of energy. No movement of power is necessary.

> Here is a simple question: Real power = I**2/R
>
> How can real power be negative?

The use of "real" indicates that you're referring to *average* power. I'm not. If when I say "power" you read "average power", then misunderstanding is certain to occur.

> This is straight from EE101.

You apparently took a different curriculum than I did. The references I have (see the end of this posting) support what I learned, that power = v(t) * i(t), which obviously (I hope it's obvious anyway) can be negative as well as positive. Let's look at a simple circuit consisting of a series resistor, capacitor, inductor, and voltage source. The equation relating i(t) and v(t) looks like this (I don't recall the course number, but the problem appears less than half way into my elementary circuits text, so it was probably first semester circuit

analysis):

L*di/dt + Ri + 1/C * Integral(i dt) = v

If you multiply both sides by i, you have v * i on the right, which is power, and on the left you have i^2 * R for the central term, but two more terms to deal with. So it's hopefully obvious that power isn't i^2 * R. Or if not, it should at least show you that v(t) * i(t) isn't equal to i^2(t)/R. And all this without having to introduce negative time. Incidentally, the above equation is correct regardless of the nature of v(t) -- it doesn't need to be sinusoidal or even periodic. So it's as basic as they come.

If you plot the power (v * i) at some point in this circuit, you'll find that it's positive for part of each cycle and negative for the remainder of the cycle. If you do the integration of this over a cycle and divide by the period in order to get the average power, you'll find that the average power (what you've called "real power") is indeed I(RMS)^2 * R, which is positive.

If a circuit has only resistance and no way to store energy, then v(t) = i(t) * R, power is i^2 * R, and power is always positive. Negative power occurs when energy is stored for part of a cycle, then returned during the rest of the cycle, as in the series RLC circuit. Or a transmission line which isn't perfectly terminated.

A recurring problem is confusion between power, which is v(t) * i(t), and average power, which is the integral of this over one cycle divided by the period. Anyone confused by this can easily find ample study material in any elementary electrical circuits text book. The discussion of RMS at http://www.eznec.com/Amateur/RMS_Power.pdf might also be helpful in understanding the relationship between power and average power, although it doesn't deal with energy storage.

Many people learn only about average power because it's adequate for most everyday applications, and the math involved with calculating instantaneous power is considerably more involved. But anyone trying to understand the movement of energy in a system capable of storing energy really needs to understand power on a more fundamental level, as the time derivative of energy movement. And I hope it's still being taught in engineering schools!

>> It's no wonder that people are having so much trouble understanding energy
>> movement, and why it's so easy to lead them astray with red herrings and
>> pseudo-science,
>
> OMG, give me a break. Tell me about the law of conservation of negative

If you'll look in a basic physics text you'll find plenty of references to negative potential energy. That concept, however, isn't necessary in order to use and understand the directional property of power.

>> when there's so much misunderstanding about the underlying concepts and
>> terminology. If you start with concepts which are fundamentally erroneous,
>> the knowledge you build on them is bound to be wrong.
>
> Tell me how to make I**2/R a negative number that generates negative heat
> and which is not fundamentally erroneous.

I^2*R is one expression of average power, which has never been what I've
been discussing. So I'll gladly leave this proof to you.

> Yes, thuis truly is fundamental. I am rather surprized at this diatribe and
> how it exposed *your* lack of understanding of fundamental concepts.
>
> AI4QJ

I plead guilty to not knowing everything, and to always striving to
learn more. I am comforted, however, by the number of respected
professors and textbook writers who share my lack of understanding of
these concepts. For example,

1. Pearson and Maler, _Introductory Circuit Analysis_, p. 251:

"For our conventions the power to the right is p = vi. . ."
"The capital letter P is used to designate average power, whereas the
lower case letter p is a function of time. Figure 5.14 shows voltage,
current, and power as a function of time. At those instants of time at
which power is negative, energy is flowing to the left in Fig. 5.13."
The little program TLVis1 I introduced a while ago generates waveforms
for voltage, current, and power very much like fig. 5.14.

2. Van Valkenburg, _Network Analysis_, 3rd Edition, p. 420:

"The rate at which energy is being absorbed [by a one port network] is
the power given by p = dw/dt = v(t)i(t) W (watts)" Figures 14-4 and 14-5
on the following pages show graphs of the power for an inductor and
capacitor respectively which are sinusoidal and centered around zero. On
p. 424: "Energy is the integral of power. Using the convention for sign
illustrated by Fig. 14-2, we see that, for positive p, energy is being
supplied to the inductor and capacitor for storage. When p is negative,
energy is being returned to the source. We know that no more energy can
be returned than supplied, of course, and the fact that w [the energy]
returns to zero value for every cycle of the voltage and current implies
that the energy supplied ins returned entirely every cycle for the
inductor and capacitor."

I'm curious. What text did you use for your EE101 course which says
otherwise?

> transformation by the 4:1 or 1:1 balun ?
>
> Thanks de Pierre VE2PID

The impedance that your transmitter or matching network has to deal with is the differential impedance, that is, the impedance between the two conductors. A properly designed, constructed, and applied 1:1 balun will effect no transformation at all of the differential impedance. A 4:1 balun will make it either four times greater or four times less. Both types of baluns, again if properly designed, constructed, and applied, will greatly increase the common mode impedance, that is, the impedance you'd see if you connected the two feedline conductors together and measured the impedance to ground.

In reality, any transformer will usually behave reasonably well only when terminated in an impedance near its design impedance. For example, a 4:1 balun or transformer designed to transform 200 to 50 ohms will work well only if the high-Z end is connected to around 200 + j0 ohms. (Such a transformer might have a high-Z winding impedance of 1000 - 2000 ohms, and it might well be resistive as well as reactive.) If you get very far from 200 + j0, you'll find that the transformation ratio changes and the transformer adds reactance and sometimes resistance. The error can get dramatic with even moderate excursions from the design Z, depending on the transformer design. It would be a difficult job to make a transformer other than air core with a resonant winding which would do a decent job of transforming the impedance you quote. So the short answer is that it's anyone's guess what a 4:1 balun would do to that impedance. A 1:1 current balun can be made from a section of transmission line made into a coil, wound on a core, or with cores put around it. The impedance will be transformed according to well known transmission line effects, which depend on the length and Z0 of the line used for making the balun.

1706. Window line billowing in the wind

Newsgroup: rec.radio.amateur.antenna
Date: 2008-01-31 14:34:35 UTC
From: Tim Shoppa <shoppa@trailing-edge.com>
Message-ID: <ad249018-4a2f-41b7-b11d-0a6e57c5220c@f47g2000hsd.googlegroups.com>
Source record: 28677

I've got a 130-foot doublet hanging 90 feet up in the air between two trees. A pulley and a counterweight (a gallon of sand) keeps 20-some pounds of tension on the line. Not a lot of tension but works great on non-windy days. If the trees were stronger up at the top I might try a heavier counterweight, but I'm not sure I'd be comfortable doing this because I am really hanging from the treetops right now.

The feeder is approx 70 feet of 450-ohm window line (like twin-lead but with little gaps every so often) to a standoff on the side of the house. Yesterday when we were having 50MPH gusts this was billowing out like a sail. I had twisted the window line a while back after the last big windstorm, and that seemed to mitigate the sailing-ship kind of effect, but not by a lot.

The counterweight and pulley did a great job of absorbing the wind gusts. It was really impressive - when the big gusts came up, the feeder billows out, and the gallon of sand shoots up in the air 30 or 40 feet above its usual position. I'm pretty confident that as long as the trees didn't fall over in a hurricane, this antenna would stay up. I even put a real stainless pulley with bronze bearings in, replacing the one-dollar hardware store pulley, and am happy that I did. I have seen the one-dollar pulleys get visibly corroded in a year or so on a previous antenna.

But I'm thinking... if I just used two conductors of #16 copperweld and some spacers to get true ladder line as opposed to window line, would this billowing completely disappear, or drop to a tiny tiny fraction of what it is now? Or would it just continue billowing the same way?

What's preferable for such homebrew ladder line: solid copperweld, stranded copperweld, solid copper, stranded copper, ???.

Just finished putting up the antenna and included an air wound balun at the end of the ladder line per instructions. Maybe the capacitor was a shortcut to a balun? The impedance on the line in my shack varies from about 50 ohms on 75M up to about 450 on 10M. Not hard to match with my tuner.

The antenna BTW is like an inverted V, with a center on a mast up 40'. It also bends at the feed point about 30 degrees.

Most of use agree that Pload = Pfor - Pref (at the load).
There's a negative sign on average power. In fact, Ramo
and Whinnery designate Pfor as 'P+' and Pref as 'P-'.
This is simply an engineering convention concerning
direction of the Poynting vector.

The billowing depends upon the total surface area exposed
to the wind. It is akin to the wind loading specs for an
antenna. The way I solved the problem with 440 ohm ladder-
line (actually measured 380 ohms) is to buy The Wireman's
#14 stranded copper-clad steel, ladder-line product code
#554. With proper strain relief, that stuff is virtually
indestructible. It even put dents in my wire cutters. :-(

> Superposition requires that the two don't interact.

From "Optics", 4th edition by Hecht, page 385:
"Optical interference corresponds to the interaction of two or more light waves yielding a resultant irradiance that deviates from the sum of the component irradiances."

From Schaum's "College Physics" 10th edition by Bueche and Hecht, page 381: "Interference effects occur when two or more coherent waves overlap. If two coherent waves of the same amplitude are superposed, *total destructive interference* (cancellation, or in the case of light, darkness) occurs when the waves are 180 degrees out of phase. *Total constructive interference* (reinforcement, or in the case of light, brightness) occurs when they are in-phase." emphasis is the authors.

Hecht says that interfering waves interact. Bueche and Hecht say that the two coherent waves interfere during the act of superposition. I think you will find that wave cancellation requires interaction between two waves during superposition.

Let's paraphrase Hecht's words into RF lingo.

RF interference corresponds to the interaction of two (or more) RF waves yielding a resultant average Poynting vector that deviates from the sum of the component average Poynting vectors.

Most of use agree that Pload = Pfor - Pref (at the load).
There's a negative sign on average power. In fact, Ramo
and Whinnery designate Pfor as 'Pz+' and Pref as 'Pz-'.
Quoting: "... the Poynting vector for the negatively
traveling wave is always in the negative z direction
except where it is zero."

This is simply an engineering convention concerning
direction of the Poynting vector. Away from the source
is usually considered to be positive while toward the
source is usually considered to be negative.

I had a nearly identical antenna to yours, but had instead used W7FG's 600 ohm ladder line. Apparently this has a lot less wind surface area than your 450 ohm stuff with all that flat plastic between the wires because I never had the "sailing" effect you had, even in some 75mph storms recently on the Oregon coast. My stuff just doesn't have ANY flat surfaces for the wind.

You might consider switching your feedline type.

And, I might add, in the frequency range for which it's designed.
That may be obvious for something like trying to apply an audio
transformer to RF balun service, but it may not be so obvious if you
just pick up a "ham" 4:1 balun and think it's going to work for your
particular frequency range, if it's not designed for that range.

You'll _probably_ have better luck using a balun designed for, say,
50:200 ohms over 1-50MHz with a 3000-j4500 load at 20MHz than if you
try the same load impedance at 2MHz. That's because the transformer
reactance must be high enough at 1MHz to work at 50:200 OK, so there's
at least some hope the reactance will be enough larger at 20MHz to not
screw things up too badly. You will also want to watch out for core
saturation: run at lower power if the load is higher impedance. You
wouldn't want to push the balun too far toward the high end of its
frequency range, either, because there may be stray capacitances
limiting the response at the high end.

As Roy says, it's hard to say what your particular balun will do when
presented with a load so far away from the (presumed) 50:200
impedances it was designed for, unless you measure it with that load.

Cheers,
Tom

Cecil,

Unfortunately it appears that Hecht was writing for ordinary people, not RRAA nit-pickers.

OK, lets suppose waves interact, or by the dual nature, that photons interact. What are the equations that govern such interactions? I believe we generally understand gravitational force between masses, electromagnetic force between charged particles, and even various nuclear forces. There may not be a Grand Unified Theory yet, but we have quite a good set of tools to work with the known interactions. At the same time, as far as we know, photons have no mass, no charge, and none of those strange or colorful sub-nuclear parameters.

If we cross two laser beams it appears that the photons pass right by each other and continue on with no apparent interaction. You often claim that the interaction occurs only when the photons are traveling in exactly parallel paths or anti-parallel paths. OK, that is a bit unusual compared to the other forces in nature, but perhaps it happens. Even so, one should be able to describe this interaction in some specific and quantitative manner.

As a self-proclaimed scholar of quantum electrodynamics you should be able to readily identify the forces and other relationships between photons. I do not claim to be a scholar of QED, but I have looked at a few Feynman diagrams. I cannot recall every seeing one in which two of the wiggly lines representing photons simply bounce off of each other. There is always an electron or some other particle involved when the photon wiggly line changes direction

Hint: You keep ignoring the role of the materials at the impedance discontinuity, or whatever you want to call it. I have no doubt that Hecht is fully aware of the correct description, but it would be a bit pedantic to include it in an introductory level optics text or Schaum's Outline.

73,
Gene

But sometimes they 'seem' make each other partially disappear, Cecil.
What about then? Sometimes they 'seem' to make each other bigger.
Doesn't that also 'sound' like they're having an effect on each other?
All equally convincing evidence that waves make other waves do things.

It's obvious. Two waves may cancel without affecting each other in exactly the same way that A + B can equal 0 without making A = 0 and/or B = 0.

OK, I gave this some thought last night. I see a couple problems...

Though you could use 1mA meter movements, that puts you at a detected
power level high enough that the meter scale won't be linear in power,
assuming Schottky or germanium diode detectors. To me, having a
linear power scale is a big advantage, because then you can reasonably

accurately figure SWR without having to worry about temperature compensation of the detectors. There's a reason that Bird power meters use a sensitive microammeter movement. (I think I've heard 30uA full scale, but I'm not sure about that.) Anyway, that's why I suggested using a DVM for readout.

The second problem is, if you want to implement a microstrip design, how do you get the trace width right? If you're afraid of surface mount parts, how will you control the trace width to +/- a fraction of a millimeter? On 1.6mm thick PC board, assuming FR4 with a relative dielectric constant of 4.75, you'd like to have a trace width about 2.78mm to get a 50 ohm line. If your trace is 3.5mm wide, you get a bit under 44 ohms, and if your trace comes out 2.0mm wide, you get a line that's almost 60 ohms. If you can do the PC board photographically and have confidence that you can control the trace width to within 0.1mm, that would work. If you're doing it by scribing the copper and pulling up unwanted copper, I think you'll have to be working under a pretty good microscope to get to much closer than a mm of the desired width-- or maybe cut it on a milling machine.

I suppose there's still the possibility of cutting the trace a bit narrow on purpose and adjusting the impedance by adding a grounded plate above the board. It could be spaced an adjustable distance away by mounting it with threaded rods (long screws), and adjusted to make the traces 50 ohms. But there's still the problem of making the two (or three) all the same width. Not knowing how you might be able to do this, I'm rather discouraged about how this would come out. Maybe there's a better way to make the coupled lines that's easier for a typical ham with minimal shop facilities to handle. Or maybe if there was enough interest, someone could make some boards with guaranteed performance.

On the positive side, I did find BNC jacks that edge-mount on PC boards, so that part of it becomes easy at least.

Cheers,
Tom

**Pardon my ignorance, but isn't it just a case of using an op amp or whatever to suit whatever meter movement I have? ANyway, I have now sourced a 100 microamp meter (MU65) with a 3.9K resistance (sounds strange as the 1 mA one has a 210 ohm resistance.

BTW, I'n not bothered about the linear issue. I will be having two meters to show forward and relected powers simultaneously. I don't want to clculate actual SWR.

This is called residual SWR in a reflectometer. You load it with a known good load, and what SWR you find (or what is exhibited by the two meters) inhabits the reflectometer itself. Then you flip it over and apply your source into the goesoutta with the known load on the comesinna. You then proceed to reduce the residual SWR in both directions.

Finding a good load is another matter, and I reported one (a precision RF resistor) with specific characteristics here last week. Consult the thread "RF Power Resistors from Caddock."

All of $10-$20 to accomplish.

Ah, OK. I had assumed you wanted to use just the meters, with no
amplifier. With amplifiers, the 1mA meters will be fine. But we need
op amps that have very low offset voltage and drift--I would prefer to
set the meter full scale to correspond to around a millivolt or two of
detected DC. I suppose if you have a way to zero the offset and it
doesn't drift, that'll be OK. Then we need to make sure the amplifier
is reasonably immune to 450MHz signals floating around... This is all
"do-able" but there are some details you'll have to pay attention to.
I'd suggest using a couple of the RF power detector ICs available from
Analog Devices or Linear Technology, but we're back to surface mount
stuff again at that point.

>

Well, yes, but wouldn't you want to know whether "0.1" on the meter
represented 1/10 the power of "1.0" on the meter, rather than 1/100 of
the power?? If you don't pay a little attention to the level of RF
the detector is actually detecting, you're liable to have that
problem.

> **But how do you check that in a workshop with no test gear?

What do you mean "no" test gear? You'll have the directional coupler with meters itself, and a power source. The only other thing you need is a 50 ohm load to put on the coupler output. Is it not worth having at least a load you can trust? With a known good load, you feed some power through the coupler and adjust for zero indicated return; turn the coupler around and make sure the other port also reads zero. With an open or short load you should get equal readings on the forward and reverse meters. (I suppose you need two couplers and a good load to insure that the through line of the coupler is also the same impedance as the load...) I have a good network analyzer on my bench at work, but without a calibration load to test and calibrate it with, I don't know how good its readings really are.

Cheers,
Tom

nit-pickers.

That's not my problem, but it appears that you have made it
yours. Seems one of the .science.physics newsgroups would be
the appropriate place to argue that Eugene Hecht is/was wrong.

> OK, lets suppose waves interact, or by the dual nature, that photons
> interact. What are the equations that govern such interactions?

The FSU web page explains it thusly: "Instead, upon meeting, the
photons are redistributed to regions that permit constructive
interference, ..."

The irradiance equation explains where the quantized energy
goes in joules/sec/unit-area. I will try to ascertain what
quantum physics says about "interaction of photons".

Here is an interesting quote from Feynman. "e - the amplitude
for a real electron to emit or absorb a real photon. ...
It's one of the *greatest* damn mysteries of physics: a
magic number that comes to us with no understanding by man.
You might say the 'hand of God' wrote that number, and 'we
don't know how He pushed His pencil'." emphasis Feynman's

Assuming that two photons interact (with an electron as the
'middle-man') I doubt that you or I can ever understand it
better than Feynman. I would make a W*A*G that if two coherent
photons with opposite phases and equal momentum are absorbed
by an electron, then two coherent in-phase electrons are emitted
in the *opposite direction* in a transmission line. It's only
slightly more complicated than ordinary quantum reflections.

> If we cross two laser beams it appears that the photons pass right by
> each other and continue on with no apparent interaction.

Yes, that is true. I have said that superposition can occur
with or without interference and that interference can occur
with or without wave "cancellation" or "reinforcement" (to
put it in Hecht's words). Proving that wave cancellation does
not occur for ten examples is obviously not good enough. You
must prove that it is impossible for wave cancellation to
ever occur. Since it occurs every time I tune my antenna
tuner to cancel reflected waves toward the transceiver,
good luck on that one.

> You often claim that the interaction occurs only when the photons are traveling in
> exactly parallel paths or anti-parallel paths. OK, that is a bit unusual
> compared to the other forces in nature, but perhaps it happens. Even so,
> one should be able to describe this interaction in some specific and
> quantitative manner.

A forward wave normal to a surface (where the index of
refraction changes) results in a reflected wave that is
also normal to that surface and traveling in the opposite
direction. That fact of physics is explained in every
optics textbook that I have ever seen. There is no easily
measurable voltage associated with a light wave, so irradiance
is used to measure the intensity of the light wave.
Superposition allows us to introduce a second light wave.
The interference term in the total irradiance equation
describes things in a quantitative manner when two coherent
waves are superposed.

> As a self-proclaimed scholar of quantum electrodynamics you ...

I am afraid you have me confused with someone else.
It was you, not I, who paraded your credentials in
front of this newsgroup so everyone could see how
omniscient you therefore must be. I am but a
grasshopper, trying to learn something new in the
process of correcting my mistakes.

> I cannot recall every seeing one in which two of
> the wiggly lines representing photons simply bounce off of each other.
> There is always an electron or some other particle involved when the
> photon wiggly line changes direction

The wave reflection model is compatible with quantum
physics. Since wave cancellation can only occur at
an impedance discontinuity (a changing medium interface)
there are always electrons around to act as "middle-men"
especially in a copper transmission line.

> Hint: You keep ignoring the role of the materials at the impedance
> discontinuity, ...

NO! I DO NOT! You guys seem to have an obsessive-compulsive
tendency to falsify what I have said. I have said numerous
times that wave cancellation can *ONLY* occur at an impedance
discontinuity, i.e. a change in mediums, where materials do
exist.

Who is forcing you into ad hominem attacks and innuendo in
order to present your case?

Sometimes when I shoot at a target I hit it and sometimes
I miss it. I guess nature doesn't work that way either?

This discussion reminds me of Dr. Best's phantom waves
that keep on traveling and existing forever while both
E-fields and H-fields are equal to zero for all space-time.

>> If the waves
>> disappear from existence, they had an effect on each other.
>> If they don't disappear, they had no effect on each other.
>
> But sometimes they 'seem' make each other partially disappear, Cecil.
> What about then?

More information that "seem" is required to answer your
question. A magician "seems" to make the rabbit disappear.

Sometimes they actually do make each other partially disappear.

If P1 = P2 = 100w and the wave E-fields are 135 degrees
out of phase, the resultant wave contains:

100w + 100w + 2*SQRT(100w*100w)cos(135) = 58.6 watts

Assuming steady-state and multiplying both sides of the
equation by one second:

Where did the other 141.4 joules go?

In the interferometer example, the two waves cancel
for all of steady-state at the standard output and
the reflected energy back toward the source due to
that cancellation is intercepted and presented at
the non-standard output. If the two canceled waves
don't affect each other, why do their combined
energy components appear later at the non-standard
output? What reversed their momentum at the standard
output?

Can you define what you mean by linear? Straight line?
Since we can only measure voltage and current, in order
to obtain a linear power scale from a linear meter, it
is necessary to supply some pre-display computing
ability (microcomputer).

> Where did the other 141.4 joules go?

The fact that you would even pose that question in the first place indicates that you have made a false assumption. What did you assume about the 200 Joules/sec that turned out not to be at all true?

Sorry, that is a false statement and just another one of
your numerous straw man diversions. If waves interact enough
to cancel either entirely or partially, they have interacted
100%.

> One might get the feeling that you're making this stuff up as you go along.

No, I have been consistent. You, OTOH, appear to be engaging
in your usual obfuscation, e.g. "disappearing" doesn't mean
mean the same thing as "cancellation".

See earlier posting in this thread. See various Avago ap notes, such as AN 969. A diode detector run at low input provides an output DC voltage that's a constant times the square of the input RF voltage. If the input voltage is, or is assumed to be, at some constant resistive load impedance, the DC output is linear with RF power input. The proportionality is temperature dependent, but if two detectors are constructed the same and run at the same temperature, and run in the signal level region where that relationship holds, then the ratio of the output DC voltages is a very good approximation of the ratio of the input RF power levels, and thus is useful for finding the SWR if the detectors are attached to the forward and reverse ports of a good directional coupler. Top end of the useful "linear power" range using an HSMS-2850 single diode detector is about 10mV DC output. If you can measure the DC accurately down to 1uV (a bit tough, given thermal emfs, but possible), that gives you about a 10000:1 power range, or 100:1 RF input voltage range -- or about 1.02:1 SWR. Chances are very good that a home-built coupler won't be accurately enough matched to 50+j0 ohms to worry about anything that low anyway, even if you had a reason to care about it.

Cheers,
Tom

Hi Cecil -

An interferometer uses partially reflective mirrors. Assuming perfectly flat mirrors, perfectly collimated, monochromatic, coherent light that is normal to the surface, when the separation between mirrors is an integer number of half wavelengths of that light, light is canceled in the reverse direction, and all the light from the illuminating source (less losses) passes through the mirrors. Some of that light passes directly through them, and the rest passes through after multiple internal reflections.

The two books that I have purchased on this subject are "Fabry-Perot Interferometers", by G. Hernandez and "The Fabry-Perot Interferometer" by JM Vaughan. Both of the texts are well in excess of 300 pages, so any explanation one might give here would lack significant detail. There's nothing in them about waves causing other waves to do things. The books do however describe in great detail how interferometers do things to waves.

Tom,

This is further from Suzy's needs, but...

Operation of a diode detector in the square law region isn't out of the question, but it takes some serious gain to drive a meter. There are some good chopper stabilised op amps out there that have uV offset levels and single supply rail and input to below the negative rail eg LTC1050.

Another alternative is the AD8307AN log amps for a linear dBW scale. You could even use one on FWD and REF detectors and difference the outputs in an op amp for a direct indicating VSWR or RL scale. I have thought of getting one of these chips and seeing whether its response is fast enough to drive a PEP amplifier for SSB telephony.

Back to Suzy's problem...

The instrument downstream of the sampler is not so much the issue as building and calibrating a sampler when you have no test gear.

Suzy, if you see a Revex W560 going on VKHAM for $100 or so, it is a good buy. It has HF to 70cm (two independent couplers, ie four coax connectors), and works pretty well.

For a dummy load, the market was flooded with terminations from 25W to about 60W that had been scrapped from AMPS base station equipment, and they were sold at hamfests for $20 or so, you may find them if you look around.

Owen

Roy, your references and your own statements are only saying that, yes, it can be or usually is an engineering conevntion to put a minus sign in front of P to indicate direction. I violently agree! As you know, quoting from my preceding post:

"Of course anyone can assign a relative sign in front of a power quantity.
For example, it might be convenient to assign a minus sing to reflected
power to distinguish it from forward power. But in no way does assigning a
minus sign as a means to signify "reflected power" also mean that the power
is "negative". It simply means positive power moving in the negative direction!"

Then you proceeded to go through all the trouble to cite beginner engineering textbooks (I guess that's an insult or something) in which this was, in fact, being done. Fine. Obviously I agree because I said the same thing in the preceding post.

What you originally disagreed with me on was my statement that there is no such thing as "negative power". On a relative scale, there obviously is such a thing as positive power going in a direction that we define as positive and also the opposite direction that we define as negative. But in terms of an absolute scale or reference there is *no such thing* as negative power. We cannot remove heat by passing current through a resistor. Why is this important? Because in this discussion people were getting confused and started adding and subtracting powers as if they were conservative field vectors (such as voltage). Power can only be vectored by it's direction of movement. It is not a field vector. The point is (pardon the pun), to superimpose waves you must do so only with field vectors, not directional vectors, or in the very least you cannot mix the two. There is no power "vector" which can reduce to zero by adding a positive power to a negative power. At the point where you add the positive and negative powers, does it cancel to zero? No, it quadruples! I can assign a negative sign to all money that is no longer in my bank account; that does not mean it is negative money, it is still positive money but it exists elsewhere. This is extremely fundamental. It is like I am saying there is no such thing as negative temperature, that is, below the reference of absolute zero. Then Roy comes back and says "Oh yes there is, the temperature outside was -15F last night. My Textbook

says that, for the purposes of this book, all references to degrees shall be in Fahrenheit. There obviously is a temperature below 0F which is negative, thus negative temperatures must exist." If you can just bridge the gap between relative to absolute, then you will partially understand why you cannot add power "vectors" like you can add vectors from a conservative field.

You really should seek help. What was this supposed to mean?

"If the waves disappear from existence, they had an effect on each other.
If they don't disappear, they had no effect on each other."

You can't just make things up as you go along, Cecil.

So first you claim that you made absolutely no assumptions in solving
the problem, and then for good measure you throw another insult.

So. In posing the question are you not assuming some energy is
missing? Are you not assuming that power has a phase angle? Are you
not assuming there is a physical discontinuity? Are you not assuming
a one dimensional system? I already know the answer, so you needn't
bother.

I'm done.

> about Poynting's Theorem?

The dash indeed does indicate a vector which is an average
value. It says, "E and H are the electric and magnetic field
vectors in phasor notation." My dictionary does not define
"Poynting's Theorem" but it does define the instantaneous
Poynting vector, as opposed to the average Poynting vector,
as ExH. (I have never found the instantaneous Poynting vector
to be of much usefulness in ham radio).

The average Poynting vector matches up well with RMS values
of voltage and current with which we all are familiar.
Obviously, Vrms*Irms = (Vmax*Imax)/2 = Re(ExH*)/2
for traveling waves.

If the diode is DC-biased and the bias subtracted out
during calibration, doesn't that improve the low power
accuracy considerably?

Let me rephrase that statement so even you can understand it.
If the waves disappear from existence in their original
direction of travel, they had to have an effect on each other.
If they have no effect on each other, they cannot disappear
in their original direction of travel. (Of course, you knew
exactly what I meant and did your usual nit-picking, word-
twisting act hoping to hoodwink the uninitiated.)

> So first you claim that you made absolutely no assumptions in solving
> the problem, and then for good measure you throw another insult.

No, I claim that I made absolutely no *false* assumptions
and then questioned your more-than-obvious lack of proficiency
in the English language.

> In posing the question are you not assuming some energy is
> missing?

Absolutely not! You are the one who keeps introducing missing
energy - so you must believe in it.

> Are you not assuming that power has a phase angle?

No, the E-fields of the two waves have a phase angle.
Quoting my years old "Worldradio" article:

"Powers, treated as scalars, are incapable of interference.
Any sign associated with a power in this paper is the sign
of the cosine of the phase angle between two voltage phasors."

But since that statement is a result of your suggestions
years ago, you already knew that your above accusation
was just bafflegab-obfuscation on your part.

> Are you not assuming there is a physical discontinuity?

AFAIK, wave cancellation is not possible without a physical
discontinuity. If you can prove wave interaction at a point
removed from a physical discontinuity, please present it.

> Are you not assuming a one dimensional system?

An RF transmission line is essentially a one-dimensional
system - or a 1.1 dimensional fractal system if you prefer.

Having been told so by two of you, looks like I'll have to trade a rolling pin for a "known good load". Trouble is, there's probably no source here in Australia.

Not necessarily true for a coupler..

The proportionality is temperature dependent, but if two
> detectors are constructed the same and run at the same temperature,
> and run in the signal level region where that relationship holds, then

where "good" is the operative word

Top end of the useful "linear power"
> range using an HSMS-2850 single diode detector is about 10mV DC
> output. If you can measure the DC accurately down to 1uV (a bit

> accurately enough matched to 50+j0 ohms to worry about anything that
> low anyway, even if you had a reason to care about it.

Which is why "real instruments" have some form of calibration. With
today's technology, there's really no excuse for not putting some form
of calibration into the logic between measurement and display, unless
all you're looking for is the RF equivalent of a battery and test lamp.

Heck, if you MUST use all analog designs and you're at less than 3GHz,
don't fool with diodes, use the less expensive, more sensitive, and more
accurate power measuring chips from Analog Devices.

Example: AD8310, DC-440MHz, 90+dB dynamic range (-91 to +4dBm) linear to
0.4dB, stable over temp(-40 to +85) +/-1 dB

or the 8319, 1MHz to 10GHz, 40dB range, similar accuracy

they also come in dual versions and versions with phase comparators..

These days, there's relatively few applications where a straight diode
detector would be better:
1) Absolute lowest cost in mass manufacturing with relaxed performance
requirements(so you can use a really cheap silicon diode)
(0.10 for a diode vs $3 for a chip is a $30 difference in the retail
list price)

2) very fast rise time requirements
The chips have response times in the 10 nS and slower range. The right
diode in the right mount can get sub nanoseconds.

3) frequencies >10 GHz
The chips don't go there yet.

Thanks Owen. BTW, what type of coax connector? Not PAL surely!

At the risk of thoroughly boring you all, I'll summarize the position to date. I have a good workshop with power tools and I like metal bashing and am quite happy with PCBs. I even have an electronic calliper so can measure thickness accurately. However, my eyes will not allow very fine work like SMD. I am looking to build an SWR meter using two 1 mA meters, one for forward and one for reverse. I am looking for a practical (non-theoretical) article on how to build one. I am wondering if there is one the ARRL handboook before I go to the exp-ense of buying one here in Australia. Most of the beautifully argued theory on here is way way beyond me. Any pointers to a suitable article?

I don't think I can make any more positive contributions to this discussion, except to remind readers that I have never, ever promoted the idea of adding powers, vectorially or otherwise, or to treat them with superposition. In fact, I've shown mathematically several times why this can't legitimately be done.

Thanks very much for that, but I am hoping to get a Bird Termaline 50W dummy load, which I hope will enable me to progress. Thank you all for holding this floury (not flowery!) hand.

And further to that, I am hoping to shortly get a Bird Termaline 50W dummy
load, so I'll have something to work with!

We have two completely separate experiments running with one
amp flowing through a one ohm resistor. Each experiment is
dissipating one watt. Roy is telling us that two experiments
taken together do not dissipate two watts. I, for one, would
like to see proof of that assertion.

No, but they are not all that bad. Almost no one manufactured VHF land
mobiles here with UHF connectors, but they did use PAL (Belling & Lee)
once (Pye Reporters for instance).

Suzy,

I had a look at Farnell (au) for these type of resistors recently
(Caddock are not the only maker).

My recollection is that a 100W resistor is likely to be good for 50W -
60W in a practical application, and they were about $28 ea + $12
shipping, and IIRC minimum order quantity was one.

That is not to recommend them for a simple accurate load for 70cm.

Owen

One might find that you can BUY a surplus directional coupler for 440MHz
fairly cheaply. Check Ebay, etc.

Then it's just a matter of wiring up electronics to the coupled ports.

in AU, have you checked surplus places like
http://www.users.bigpond.com/alandevlin/forsale.html

Indeed, it shows a HP 774D as being sold, but perhaps he'd have other stuff.

I think it is rated to 3GHz, look after it and it will be very useful.

People tend to overlook the value of a known dummy load, it is a very useful piece of test equipment, and one of the first you should own.

If it is used, take the opportunity to test it some time.

With that in you kit, you have a chance of calibrating a VSWR meter sampler.

You might find the following article of interest, skip the maths if it gives you a headache, but the discussion towards the end is relevant to setting up / testing a VSWR meter: http://www.vk1od.net/VSWR/VSWRMeter.htm
.

Perhaps you have some trusted ham neighbours who can help you out.

Owen

Cecil,

Did you ever toss a ball against a wall and observe it come back at you? By the ordinary rules of mechanics the momentum of the ball changed significantly. Also by the ordinary rules of mechanics the momentum of the wall changed just as much. Did you see the wall move? How much kinetic energy do you suppose it required for the wall to move at, say, one femtometer per second?

Concern about momentum in HF waves is pointless. There is virtually unlimited capacity for the interface to source or sink any necessary momentum.

Cecil,

I am curious why you find the Poynting vector as you described above to be useful at all for ham radio. It appears to be merely a synonym for V*I in some form.

In the standard TEM mode in a coax transmission line the H-field is represented by a set of concentric rings around the center conductor, while the E-field is a set of radial vectors from the center conductor to the outer conductor.

Do you actually calculate the cross product of those vectors to determine the Poynting vector? If so, I would be quite impressed. If not, what is the Poynt of the Poynting vector in your definition?

That's exactly why it is useful. It links the E-field
to voltage and the H-field to current.

Even in circuit analysis, negative resistance is allowed. In that case,
negative power follows automatically. In field theory, there are such
things as Poynting vectors which, to engineers at least, represent a

power density field in space. Poynting vectors can be integrated over the surface of a volume of space, giving the total power entering or leaving the space, and the directions of the vectors are important. If you have 1 watt entering a volume, and 1 watt leaving a volume, the total amount of time rate of energy entering the volume is zero. No one is trying to use power superposition. Even Cecil knows better, now. Finally, all vectors have direction. If it doesn't have direction, it isn't a vector. There's no such thing as a "field vector" that doesn't point somewhere. An E field is a vector field. It obeys the rules of superposition, so you can add vectors to your hearts content, just as with an H field. Maybe you should go back to the books defining vectors.

There's more to it than that. I think Born and Wolf may
be one of your Bibles, Cecil. You might want to read
section 1.1.4 "The energy law of the electromagnetic field"
for more insight. (I've got the seventh edition.)

The entire chunk of glass provides all the momentum source or sink
needed. Does that AR glass move every time you shine light at it? How much?

I have no disagreement with Hecht. Of course energy and momentum are
conserved. I am merely pointing out that there is not the slightest
problem in conserving momentum in any of these configurations.
Conservation of momentum in a transmission line or in a thin-film
coating on glass does not provide any useful guidance as to whether a
model is correct or not. The relative magnitudes of the numbers are such
that one could not find a momentum discrepancy even if it existed.

You continue to ignore the interface. OK, you don't actually "ignore"
the interface; rather you merely give it mention without really using
any of the properties.

> to voltage and the H-field to current.

Yes, it links the fields. That still does not explain why it is useful for ham radio. Frankly I cannot think of a single thing that the Poynting vector provides in these simple transmission line cases that cannot be readily defined in a parallel manner using voltages and currents. (And you don't really look at the H-field and E-field in a transmission line, do you?)

The Poynting vector is useful when there are no voltages or currents, for example in free space, and in other complex configurations. I cannot see that it is anything more than high-falutin jargon when it is merely a replacement for V*I in a transmission line.

Do you have any examples where a Poynting vector provides more information or better quality information than the usual voltage and current formalisms?

I will learn whatever I need to in order to be an effective radio operator when that is what is really needed. I've already set up a Winlink2000 gateway just to learn how. I've got a portable packet set up worked out using just an HT, a readily portable TNC, laptop computer, and a portable J-pole. I'm scheduled for my Skywarn class and I'm enrolled in the Level 1 Amateur Radio Emergency Communications course and I plan on taking all three courses and the needed exams to become a certified emergency communicator. I think I can honestly say I'm willing to learn.

What I was hoping to find was operators who have already used one or more of the antennas I was asking about who would be willing to share their experience of the effectiveness or lack of same with me.

You are up to your old tricks again. I have seen you do this before. You have me cornered into the position of making me prove the negative, i.e. that RF radiation has no interaction with sound (I will ignore for the moment the rather elementary side-line challenge of defining "sound" in scientific terms, particularly since you say this is not on topic). Forcing one to prove a negative is a particularly effective debating technique. Obviously I will not attempt to achieve the impossible and prove the negative using simple deductive logic. To use the more complex inductive logic and show that there is negligible probability of there ever being an

interaction is, in my opinion, much too tedious an exercize for the insignificant benefit of proving that I am right in a usenet thread. And you know that too, of course.

On the other hand, if your assertion is true, i.e. that there is an interaction, then you should be able to easily prove it through simple deductive logic using laws based on science. Your contribution would be of great interest here. However, it is perfectly understandable should you decline because I, after all, made the assertion of the negative in the first place so I am out of form turning the argument back to you. You can merely say, "I don't have to prove anything; you are the one who made the assertion in the first place". Since winner takes all, congrats!

Right, and I'm saying that with a coupler or sampler that picks off, say, 1e-7 of the power (0.2 milliwatts of RF out for 2000 watts in/through), a diode detector that shows that power to be full scale on a linear meter will show 1000 watts at half scale. That assumes that 0.2 milliwatts is low enough to get you into the square law region of the detector; for an HSMS-2850 diode, that's a bit high. Because the power at which the square law holds accurately is so low (and the detector output is so low) you need an electronic way to read that output; a simple meter movement isn't likely to do the trick. But there's no need for any fancy processing.

Yes, there are several linear-in-dB RF detectors out there. Linear Technology also have them. I really like that idea; they're typically much more temperature stable than a diode detector. But Suzy wanted to avoid SMT.

I've used a Harris chopper-stabilized op amp with HSMS-2850 zero-bias detector diodes, and it works well, but I did learn something about the need to be really careful around the chopper capacitor pins on that op amp before getting it right... But it's also not difficult to find a digital voltmeter that will go down to pretty low voltage at high impedance. A 4.5 digit meter on a 200mV scale does ten microvolts, and the simulation I ran last night suggests you could see down to about -50dBm power level with that. When you get down to 10uV, you have to get serious about avoiding thermal emfs.

I suppose it makes sense to just drive the detector hard and run it right into an analog meter movement, and then calibrate the meter.

Actually, at that level, the detector should be pretty linear in voltage. That actually makes it easier to detect down closer to 1:1 SWR anyway.

I posted not too long ago about a load I made with four 200 ohm 2 watt metal oxide resistors that shows what to me is remarkably good return loss out to well beyond 450MHz. It was very cheap to make. But there's no guarantee that some other brand of resistor would give such good results. It may have just been a fluke that the one I made turned out so good. (But I'm not about to toss it out!)

Cheers,
Tom

Hi Dan,

You've seen me do "this" before; and yet by this admission, you
entered into it with your eyes open. Are we to imagine that I am that
crafty, or that you are that gullible?

>Forcing
>one to prove a negative is a particularly effective debating technique.

Would I, by this my observation above, be "forcing" you to prove the
negative: that you are not gullible? I will not hold you to proving
the positive that I am too crafty as I have caught you again. ;-)

>Obviously I will not attempt to achieve the impossible and prove the
>negative using simple deductive logic. To use the more complex inductive
>logic and show that there is negligible probability of there ever being an
>interaction is, in my opinion, much too tedious an exercize for the

Who asked for proof?

>On the other hand, if your assertion is true, i.e. that there is an
>interaction, then you should be able to easily prove it through simple
>deductive logic using laws based on science.

Deductive logic? You are walking on stilts to achieve this specter.
As I said, the interaction is so commonplace that it hardly demands
exceptional proofs and logic.

>Your contribution would be of
>great interest here. However, it is perfectly understandable should you
>decline because I, after all, made the assertion of the negative in the
>first place so I am out of form turning the argument back to you. You can
>merely say, "I don't have to prove anything; you are the one who made the
>assertion in the first place". Since winner takes all, congrats!

It's called heat.

>>>This implies that the mystery of sound can only be comprehended by
>>>practitioners of the arts and certainly not by a mere electrical engineer.

Heat is the common comprehension of the interaction between radiation
and sound that is accessible to every engineer. Now, if you want a
more elaborate answer, complete with math, logical proofs, and at
least 40 years of science (the oldest of references on my shelf); you
can invite that by further enquiry. However, it comes with its own
terminology, its own measures, its own mechanics - none of them
unfamiliar to the engineer, just not assembled in the standard canon
of engineering (it's called Physics).

And this is not the first time I've broached the topic, but it is one
that is met with a universal HUH?

Still and all, to say
>>>>A sound wave is an
>>>>air pressure wave (it does not propagate in a vacuum)and is in no way
>>>>comparable to a radio wave, which is electromagnetic and does. I don't
>>>>believe the two interact in any way.
is not the TRUTH, it is merely a limited perception. I am not
faulting anyone for TRUTH's sake (I didn't elevate it there in the
first place), I merely pointed out that such elevation without care
cheapens truth.

As marginal as my counter-argument is to the common fare here, the
original statement also bore no more relation to the common fare.
However, both bare upon the nature of waves at the extreme where few
are vested with experience. As such, then yes this topic is
comprehended only by the practitioners of the arts and as I cited in
another attenuated thread, there is probably an audience of one other
who can follow this, or who cares.

OK, here's non-theoretical, practical.

Get a piece of FR4 PC board material, copper-clad both sides, 50mm wide by 110mm long (neither of these is very critical, but should be at least that long) by 1.6 mm thick. One side will remain all copper clad, as a ground plane. On the other side, fabricate at a minimum three traces, as follows. To make it easier to describe, assume you are looking at the board with the 110mm dimension horizontal and the 50mm dimension vertical.
Trace 1: the through-line. It will run the length of the board (110mm), centered between the two sides. It will be as close as you can make it to 2.9mm wide, uniform width from board edge to board edge.
Trace 2: It will also be as close as you can make it to 2.9mm wide for its whole length. The following is the center-line of the trace. Start at the top edge of the board, 9mm from the left side. Go down to 9.0mm above the center-line of the through-line trace (Trace 1). Turn toward the right edge of the board and follow parallel to trace 1, staying 9.0mm center-to-center. Thus there should be a gap of 6.1mm between the two traces. Go a distance of 92mm. Turn toward the top of the board, and extend the trace all the way to the top.
Trace 3: It will be the mirror-image of trace 2, same 2.9mm width. It will start 9mm from the left side at the BOTTOM edge, go up till its centerline is 9.0mm from trace 1, follow trace 1 to the right for 92mm, and then return to the bottom edge of the board.

Mount an edge-mount BNC connector to each end of trace 1, shell to the ground plane and center pin to the trace. Failing that, do something equivalent with coax or connectors...if you trimmed the end of a piece of coax so the braid connected to the back side of the board and a very tiny stub of exposed center conductor could be soldered to the end of trace 1, that should be OK.

You'll need two 50 ohm load resistors. 1/4 watt is plenty. Since 50 ohms is not a common value, you may wish to use two 100 ohm resistors in parallel for each of these 50 ohm guys. Solder one of them so it

connects with vanishingly short leads between the RIGHT end of trace 2 (at the top of the board) to the back-side copper immediately opposite that point. The resistor(s) will be soldered to points immediately opposite each other, front and back side. Solder the other 50 ohm resistor between the LEFT end of trace 3 (at the bottom edge of the board) and the back side of the board. Those are the termination resistors, and they are the ones you would adjust to get the best null when feeding power through trace 1 to a good 50 ohm termination.

Now you'll need two detector diodes (maybe Owen can help out here; I'd use some surface mount schottkys, but...) and two small ceramic capacitors. 100pF would be a good value, but it's not critical. All leads should be so short you have trouble seeing that there's any lead there at all. Solder one lead of a capacitor to the LEFT end of trace 2 (at the top of the board), and one lead of the other capacitor to the RIGHT end of trace 3 (at the bottom of the board). Those are the ends without resistors. On the back of the board immediately behind where you soldered the capacitors, solder the ANODE of a diode, one for trace 2 and one for trace 3. Arrange things so that the free lead of the capacitor and the free lead of the diode (the cathode) come together off the edge of the board. OK, I lied: leave enough lead to solder another part to, there.

Now get or make a couple small RF chokes, about 100 nanohenries. The inductance isn't critical. The way I'd do it is to wind some magnet wire onto a small machine screw. For example, try about ten turns on a 4mm screw. The wire diameter should be roughly 1/2 to 3/4 the screw thread pitch. You can then unscrew the screw and if you're careful with it, the inductor will be reasonably self-supporting. Next, you'll install these two and a couple more capacitors. Small ceramic capacitors, say something in the range from 100pF to 1000pF, should do nicely. With the board turned over so the back is now facing you, solder one side of a capacitor just a bit in-board from where you soldered the diode anode for trace 2. Do the same for trace 3. Now connect an RF choke (inductor) between the diode-capacitor junction and the free lead of the new capacitor.

You can make things a bit more robust if you mount some sort of terminal or pad on the back to solder this last junction to. One very cheap but effective way to do it is to cut out some squares of PC board material, maybe 5mm on a side, and glue them down to the large board wherever you want an electrically floating terminal.

Just about done now! Just connect a wire from each of those last capacitors (where wired to the inductors of course) to the + terminals of the two 1.0mA meters, and return the meter - terminals to the board back sides. Provide a case as you see fit, though it's usable without a case; just be careful of the parts hanging off it.

After you build it, we can lead you through calibrating it, assuming the earlier descriptions here weren't clear enough.

And I trust several lurkers will proof-read this and find all my mistakes and places where I wrote LEFT when I meant RIGHT, etc. Oh, and the meter connected to trace 2 will measure the power from left to right in the original orientation; and the meter connected to trace 3 w2ill measure power from right to left.

Cheers,
Tom

The problem that you have with FR4 is that the dielectric constant is not well defined. Your assumption of 4.75 may be ok from one manufacturer and one batch, but other examples can differ widely.

N2PK has published a nice reflectometer design using two AD log chips as detectors for forward and reflected power. The output voltage of each detector is accurately proportional to log(power) over a very wide range of applied power levels. Subtract the output voltages of the two detectors in an op-amp, and you have a direct indication of return loss in dB.

Details are at www.n2pk.com (better known as the home of the N2PK Vector Network Analyser).

By the way, the Analog Devices samples service is also open to amateur experimenters (by company policy) so by all means let's make use of it. Many devices are only available in SMD - and many advanced RF devices simply wouldn't function in a larger package - so as amateur experimenters we have to bite the bullet and learn to handle SMD.

As Tom says, SMD can be the key to accurate measurements at VHF and UHF, because the smaller packages have much lower parasitic inductance.

I wouldn't presume to tell Suzy (or anyone else) what they can or cannot see and handle; but for many people, converting to SMD is mostly about having the right equipment - a small soldering-iron tip, small-gauge solder, a good pair of tweezers, and above all, some kind of optical aid.

If they work for you, one of the best bargains would be a pair of very strong half-moon reading glasses, worn as a "preamp" on top of whatever eyeglasses you already wear. It's certainly worth wandering into the drugstore to try some (pick the strongest they have). Otherwise, there are many other sources of hands-free magnifying visors. Whoever you are, see what will work for you.

For people who are acutely short-sighted, ignore most of the above and simply take off your eyeglasses. At last, your day has come.

Under the magnifier, it's amazing how most people's hands become steady and tremor-free. (That's in the absence of any medical condition that can interrupt the eye-hand feedback loop - and also in the absence of a much more common problem: too much caffeine!) We can't all be neurosurgeons, but we can become good enough to handle SMD.

And then, as with most manual skills, it takes practice to become really good at it. For occasional SMD work, it also takes practice to get back into it after a long break.

The bottom line is that most of us CAN handle SMD... and if we don't want to become stuck in the late 20th century, we're going to need to develop that skill.

>they also come in dual versions and versions with phase comparators..
>
The last time I looked, the device with the integrated phase comparator had fallen off the regular samples service ("contact AD")... does anyone know more?

Tom, if I had said what Roy said, six gurus would have
jumped on me like tumblebugs on cow do-do.

Contrary to what Roy asserted, this "adding of powers"
can "legitimately be done" in many cases.

In a DC circuit with multiple parallel and series
resistances, the total power in the circuit is
simply the sum of the powers in the individual
resistors.

Some get into conceptual trouble when there
is interference present. Optical physicists solved
the problem centuries ago with the irradiance equation
containing an interference term to compensate for the
level of interference.

Gene Fuller wrote:
> The relative magnitudes of the numbers are such
> that one could not find a momentum discrepancy even if it existed.

The question is not how much momentum exists but if it
exists at all. I'm glad to see you admit that momentum
exists. If it exists, it must be conserved. What is the
mechanism that conserves the energy and momentum at a
Z0-match where 100% of the rearward traveling reflected
energy is routed back toward the load as a component of
the forward wave? This 100% redistribution occurs when
the physical reflection coefficient is, e.g. 0.7 as if
the reflection coefficient was 0 in one direction but
1.0 in the other direction. I don't believe in AC diodes.

> OK, you don't actually "ignore"
> the interface; rather you merely give it mention without really using
> any of the properties.

On the contrary, I use the properties of the interface every
time I calculate the reflection coefficient. Without the
reflection coefficient based on the properties of the
impedance discontinuity, I could not begin to solve the
problem.

Just jumping in the middle of ths, but look at this watt meter.

http://bama.edebris.com/manuals/miltest/an-urm120/

It has a linear scale. I have one and it has a linear scale. Sort of made like a Bird meter but much larger elements. It is just a diode and meter. There is no power needed to run the meter except the sampled power comming off the transmission line.

There were several versions made. One has a SWR scale on it. I am not sure how the swr scale is but the wattmeter scale is linear instead of the log looking scale of the Bird and most other meters.

Since the Poynting vector is a power density, it is useful
for tracking the energy through the network. You, and others,
won't allow me to use V*I in a transmission line so I was
forced to use the Poynting vector instead.

Cliff

Have a look at Lloyd Butler VK5BR's article below as he covers in some
detail the idea behind the balance capacitor and importantly a basic test
arrangement to confirm its effectiveness.

http://users.tpg.com.au/ldbutler/Zbalance.htm

Oh and I'm pleased that someone has look at my web page! I have just moved
to Western Australia and have put a new and slightly improved site due to
the new call. See blow. I will add some additional information regarding the
balance capacitor feature on the Z-match.

> Tim N3QE

Hi, Tim.
I don't think you will want to use copperweld of any size for open
feed line. The wire will twist on itself in an uncontrollable manner.
Even with closely spaced spreaders, it will still be a mess.

I had then same problem with constantly windy conditions and window
line like you are using. One wire would break about once a year and I
would have to bring the antenna and feedline down and try to find the
break. We don't have real trees here in the Central Oregon desert, so

I use 4 section masts.

When we moved last year to a bigger place, I decided to put up a 160 meter lazy quad or horizontal loop and home brew 600 ohm open line to feed it at a corner. I am still using 4 section masts, putting the antenna at about 35 feet, but I used almost 125 ft. of feedline from the house to the antenna. There are two supporting poles for the feedline run, plus a rope and pulley for the house end.

I bought a 300 ft. roll of #14 copper motor winding wire on Ebay. It has nylon or something similar for insulation. I doubled the wire by tying one end to a fence post and walking out till I hit the end of the wire, then brought it back to the post and tied it. I wound the doubled wire back on the reel. I had a bunch of phenolic rods about 1/4 inch in diameter that I cut to 6 1/2 inch length. I drilled a hole large enough to pass the wire about 1/4" in from each end of a rod. Then I spent several evenings threading the rods onto the doubled up copper wire. They were all bunched up together at one end. A real pain to do!

More evenings were spent in the shop creating the feed line with the spacers set at about 6' apart. I set a 2X12 plank on saw horses and the wire and spreaders on one end and an empty take up reel on the other. Each spreader is tied tightly to the feed line copper by tightly winding a short length of #26 copper wire on the feed wire, over the spacer and winding the rest on the other side. A blob of Duco cement was then spread on the joint. Th section of finished feedline was wound on the take up reel and then it was done all over again on the next segment. This is a lot of work, but the old way of soldering the tie wire to the feedline wasn't practical for this wire.

Eventually all was done and the feedline was installed. It works quite well and the wind barely moves the feedline. I can detect no stretching of the copper wire. Your installation may place more weight on the feedline than mine, but should still work. The soft copper does not try to twist.

Hope this gives you a little help from actual use.

Do you suppose that interface might also accommodate the necessary momentum balance? There is more to an interface than just a reflection coefficient.

The reason one rarely finds any textbook mention of momentum in wave reflection analysis is simply that it is not an important factor in solving any practical problems. The wave momentum magnitudes are minuscule compared to the source/sink capability of the interface material.

As an example of how this works, consider gamma emission from a radioactive material. A typical gamma photon has many orders of magnitude more energy and momentum than an HF photon. Yet the gamma photon shoots out all by itself. How did it find the momentum if there was no incoming photon? The answer, of course, is that the material supplied it.

The same thing happens at a lower energy scale with simple incandescence. Glowing wires emit photons without any requirement of incoming photons. Sort of like an inverse Roach Motel. Photons check out, but they don't check in.

The Wireman has #14 stranded "copperweld" in the popular
450 ohm ladder-line format.

True for Quantum Electrodynamics, but probably not for
the distributed network wave reflection model where I
cannot think of anything needed except the physical
reflection coefficient plus the irradiance equation.

> The reason one rarely finds any textbook mention of momentum in wave

What you seem to me to be saying here is: "Please don't
remind me that my methods violate the conservation of
momentum principle. I don't want to hear that."

> How did it find the momentum if there
> was no incoming photon? The answer, of course, is that the material

> supplied it.

It doesn't matter where the momentum came from. Once
it is acquired, it must be preserved.

> Photons check out, but they don't check in.

Maybe so, but the momentum in each photon can be calculated
and it must be conserved. If I remember correctly, it is
Planck's constant divided by the wavelength.

http://www.colorado.edu/physics/2000/quantumzone/photoelectric2.html

So the question remains: Given that reflected waves
exist on a feedline but disappear at a Z0-match,
exactly what is the *mechanism* that reverses the
momentum?

> in the UK? What does "PAL" stand for?

Yes, the TVs invariably have the Belling Lee connector, now known as the PAL connector. I don't know how it got the PAL label, perhaps related to its use in the UK where PAL colour encoding was used (as it is here in Oz). Apparently the PAL connector was invented in 1922 and complies with BS and IEC standards.

I did some tests on BL connectors in the seventies and performance up to 2GHz was better than UHF connectors, and quite acceptable. The BL connectors that I tested were plated brass bodied male connectors with soldered centre pin, and plated steel bodied female connectors (all in good condition).

Modern practice is to install F connectors in fixed wiring. There is a range of quality in F connectors, but the Gilbert style connectors seem reliable so long as they are done up tight with a spanner. A 'feature' of F connectors that might mitigate against widespread adoption on appliances.

On a related subject, the so called 'compression type' F connectors seem to properly terminate RG6, and are available in BNC. They are a ready and inexpensive source of weatherproof BNC termination of RG6. (Some pics at http://www.vk1od.net/RG6/index.htm .)

Hi Cliff,

It is often assumed that imbalance is caused by either sloping or the proximity of objects to one of the legs of a dipole. In my experience it is far more likely that imbalance is a result of some imbalance in the tuner or from a feedline that is not running perpendicular to the antenna over a big enough length.

I normally use a 2 coil Z-match that works quite well, but I have experimented with the single coil design and also noticed some imbalance.

Since the output coil is floating you would not expect any imbalance, but the parasitic capacitance between primary and output coil is the culprit here. That is why the effect is more pronounced at higher frequencies and relatively high differential impedances.

In the high frequency part of the two coil Z-match the centre of the primary circuit is connected to ground, so the parasitic capacitance is far less likely to cause imbalance.

Perhaps you should read up a little on fluid dynamics. Any movement in a fluid causes "shock waves" or disturbances caused by energy transfer to the fluid. The so called speed of sound is when the cause of the disturbance moves at the same speed as the propagation of the energy transfer.

Are you saying space is a fluid?

It wouldn't be near as difficult if they used spacers such as used by W7FG in his marketed 600ohm ladderline. For spacers, He uses sections of stiff plastic cut from tubing used in drip irrigation products, drills his holes, and then slits the end of the tube down to the hole so all one has to do is force the wire into the slit and on into the tight hole. No need for the difficult process of sliding spacers all the length of a run..... plus a heck of a lot cheaper, too.

It is no surprise that the Z match is susceptible to a difference in the magnitude of the voltage on each balanced port wire as described by Lloyd, VK5BR.

A possible explanation of a certain construction of the Z match circuit is that the earthy n turns of the main inductor and the output link form a two wire transmission line.

Looking at Lloyd's article at
http://users.tpg.com.au/ldbutler/SingleCoilVK5BRCct.htm , the two wire transmission line is 4*pi*62mm in length which represents about 30° electrical length at 10m. Such a phase delay suggests that lumped component analysis (eg as an ideal transformer) will probably not adequately capture the distributed RLGC nature of the two wires.

Analysis as a transmission line offers an explanation of why the currents flowing in both ends of the 'link winding' or transmission line conductor into the centre tapped load are not equal. To minimise the high end loss of balance, the transmission line section needs to be shorter, and an odd mode Zo closer to the half load Zo (but not necessarily equal to it). TL analysis also suggests a more symmetric network (with two cascaded TL sections and the earth connection between the two) that will have more equal voltage magnitued and phase changes at both ends of the TL.

The balance capacitor introduces another current path which will change the voltage across the upper half of the load, a crude form of compensation to try to extend performance.

Ouch! Very dissappointing. Nearly all forms of energy can be dissipated as heat. That does nothing to suggest any interaction at all between the separate forms of energy (for example acoustic and RF), which would require a actual unifying factor, not just a simple commonality. As you know, unification has generally not yet been achieved.

It is also a commonality with reacting H2SO4 and NaOH or the dissipation of the normal forces due to friction when braking your car. Does this suggest that sodium hydroxide in a graduated cyclinder causes either sound or radiation?

Absolutely correct! That would have been a lot easier. I even have a
bunch of the tubing I could have used. I had the phenolic rods and
could never find a use for them. For me, the fun of home brewing is
using what is on hand and only purchasing what I can't find at home.

I should say "characteristic" impedance is 377 Ohms. It also has a
permitivity and permeability of 1 ;-)

FWIW, Davis RF (http://www.davisrf.com/) has it for less...

Davis RF:
PN = LL450-HD
< 100 ft = $0.42/ft
100 - 499 ft = $0.39/ft
500 - 999 ft = $0.37/ft
> 999 ft = $0.35/ft

The Wireman:
PN = 554
< 100 ft = $0.55/ft
100 - 499 ft = $0.44/ft
500 - 999 ft = $0.418/ft
> 999 ft = $0.396/ft

However, the OP was interested in rolling his own. Again, Davis RF beats
The Wireman on price.
Description = 14AWG, 19 strand, tinned copper clad steel...

Davis RF:
PN = WM523
< 100 ft = $0.16/ft
100 - 499 ft = $0.13/ft
500 - 999 ft = $0.12/ft
> 999 ft = $0.11/ft

The Wireman:
PN = 523
< 100 ft = $0.19/ft
100 - 499 ft = $0.15/ft
500 - 999 ft = $0.142/ft
> 999 ft = $0.135/ft

Richard,

The topic was transmission lines. Otherwise the comments about voltage and current would not make much sense.

I have no issue with Poynting vectors where they are useful, for example, when considering radiation patterns in free space. On the other hand, as a synonym for V*I in a transmission line a Poynting vector is just high-falutin jargon. Now if someone really looked at the actual fields in the transmission line and calculated E x H, there would be justification for referring to a Poynting vector. Do you know anyone in ham radio who does that?

OK, that makes sense.

[Incidentally, for anyone who hasn't seen the 'alternative' meanings
for the various international color TV standards:

NTSC (USA) = Never Twice the Same Color
SECAM (France) = Something Else, Contrary to American Methods
PAL (rest of western Europe, Australia and NZ) = Perfection At Last.]

>to 2GHz was better than UHF connectors, and quite acceptable. The BL
>connectors that I tested were plated brass bodied male connectors with
>soldered centre pin, and plated steel bodied female connectors (all in
>good condition).
>
That's fine... now try again with the much more common aluminium bodied
plug, and a centre conductor wire that was pushed into the centre pin 20
years ago, was never soldered and is now heavily tarnished.

That unsoldered 'maybe-connection' inside the centre pin is a major
cause of poor reception and TVI in the UK... along with water in the
coax, which has an interesting effect when the water reaches the
aluminium/copper connection inside the plug body. The whole thing is a
classic example of insane design.

>Modern practice is to install F connectors in fixed wiring.

Much better, as those are specifically designed to be solderless.

I'm sure you mean relative permittivity and relative permeability.

The characteristic impedance is the square root of permeability divided by permittivity, so if both are one, the characteristic impedance would have to be one.

To have a linear power calibration, that has to be a square-law
detector. On the higher-power ranges, the slug is moved away from the
centre conductor, so that the diode is always operating within its
accurate square-law range.

Thanks very much for posting that link, Ralph. It's interesting to see
the resemblances to the Bird 43, and also the differences.

The Bird meter scale is not logarithmic. It's better described as being
in the transition region between a square-law detector at low meter
currents, and a voltage-detecting rectifier towards the high end of the
meter scale. The compression in the upper half of the power scale is
because the diode is acting as a voltage detector. Power is proportional
to V-squared, so the meter deflection is tending towards the square root
of the power, and that is what compresses the scale towards the high
end.

As with the AN-URM120, the Bird design adjusts the coupling so that all detector diodes in all the inserts are operating at the same RF levels, so they can all share the same meter scales. The difference is that instead of physically moving the same insert inward or outward to adjust the coupling, Bird do it by selling us more slugs :-)

Photons cannot slow down but you could be right about
them losing energy over time. Lengthening the wavelength
of a photon is certainly a loss of energy. That could
explain the red-shift of light from distant galaxies.

"Optics", by Hecht, 4th edition, Page 52:
"Photons are stable, chargeless, massless elementary
particles that *exist only at the speed of light*."

While I cannot dismiss the existence of the photons, I am not aware of
any experiments which have been able to measure them.

However, to me, the fact that there is some type of interaction with our
antennas and the ether is undeniable ... and, indeed, I do not believe
that transmission of radio signals would be possible, on most
frequencies--at least, if not for the ether.

That's what we have been doing here for the past hundred
postings or so, Gene. Any two methods for calculating
power have to agree or else one (or both) methods are
wrong.

Long ago, I used low-falutin jargon like Vfor*Ifor*rho^2
or Pfor(rho^2). There were many objections. So I switched
to |s11*a1|^2 and Poynting vectors, apparently better
established concepts supported by lots of references.

Hi All (Congratulations Ralph),

There are more differences than that. The Bird suffers more from
parts erosion than the URM120 as the URM has bigger elements. With
the bigger elements, the geometries are held to a tighter precision.

It is the coupling link that moves in the URM, not the element. The
link rides on a cam that is stepped for the 4 different power ranges
used. If you remove the knob from the slug, and then the cover plate,
you have access to an adjustment screw that provides the fine control
over the depth of penetration. The smaller PDF at the boat anchors
web page is the more useful of the two offered.

I have calibrated a pile of both the Birds and the URMs, and the URMs
always required less maintenance, and rarely needed adjustment. The
Birds, on the other hand, always arrived out of calibration.

One source of error in the VHF/UHF region was that the rubber gasket
inside the N connector (and for that matter, for any N connector) will
accumulate thread debris. It should be used as a visual correlative
to the amount of similar debris bridging the Teflon insulator. This
debris can whack out these meters and degrade connections.

I was aware of light, not RF. And, of course, at the extreme "frequencies" (others would state "Higher Energy Particles" for all RF--I guess), photons (particles) become undeniable--x-rays, gamma rays, etc. However, "light transmitters" have always been of a differing design/construction (example: light bulb) than RF transmitters.

My readings and studies have been of a "circular nature", just when I have, in the past, decided that rf are/is waves, I have read something which convinced me particles are responsible--then the opposite occurs and I am back standing on square one. Hopefully, and in a "BLATANT" manner, some experiment will make the truth of this whole subject ABSOLUTELY apparent.

Until then, I think it is OK to remain undecided and firmly set in ones beliefs ... but cautious of poking too much fun at anothers'.

Warm regards,
JS

This is what I suspected. I have SAT TV, but in the hobby/game/computer/catch-all room of the house, the TV just has a set of homemade/amplified rabbit ears. These may be able to be designed a bit different for HDTV (mainly, amp filtered for a narrower freq range(s).)

Sometimes I miss things--thinking I know all about them--or else, am side-tracked by "industry-disinformation" ... thanks for the backup.

I will keep double checking however, as with analog TV there is the pesky ~3.5Mhz color signal to worry about.

I was luckey enough to find one that was in the origional wrapping paper. I
don't remember what the date was on the wrapper. At a hamfest several years
ago soneone had several new ones. They were in the heavy duty aluminimum
foil , cardboard box, and the hard plastic foam filled case. Never opened
from the day they were calibrated about 10 or 20 years before. It came
with 3 elements that would go from about 3 mhz to 1000 mhz. Think it topped
out at 1 kw up to 30 mhz and 500 watts after that. I bought it for what
some used Birds without elements seem to go for on e-bay now.
One minor thing is the meter movement on those meters are sluggish so it
takes a slow adjustment of amplifiers to get them to the max output.

Well, my "limb" is probably well known ...

I don't think we "know" anything, until we deal with what part the ether plays in all this ... I see it as we are flying a plane without paying any heed to the existence of air--I am sure it could be done--just happen to stumble upon a set(s) of math which would allow it--it is just a "bunch easier" knowing about the air.

There aren't any VHF digital TV signals. If one lives any distance from a station transmitting in HD or SD, it is necessary to have an antenna with plenty of UHF gain. Eleven UHF elements, RG-6 feedline and an indoor, variable gain preamp give me twenty or so digital channels from my local area and from the Pittsburgh area. This works for my living room Hi-Def set or for the HD PCI card in the computer near the hamshack.

This leads me in the direction of thinking about a log periodic for the
UHF freqs in question.

If I lived in larger quarters, this would even make a parabolic within
reason.

No, this is not correct. The permitivities and permeabilities of all
materials are relative to free space. Free space is assumed to be 1 and the
other values are relative to it.

Hello Cecil,

I don't believe you can compare the two phenomena.

The photons are created because of an accelerating charge (so the photon is the wave itself, not the source that created the wave).

However, as far as I know, there is an (almost) equivalent for the airplane/air shockwave. When you shoot a charged particle (v close to c0) into a material with rel. eps >1 the particle will not abruptly slow down when entering the material with high rel.eps. So it can have a speed that is above the propagation speed of EM waves in that material. In that case an EM shock wave occurs. Look for Cherenkov shockwave.

Best regards,

Wim

Hi Ralph,

The meter needle probably has an aluminum vane in the magnetic field
that is used as a dampener through eddy current induction.

As a general consideration for fine meter movements, and to prevent
their being damaged while being transported; some are equipped with
shorting bars (or switches) across the meter terminals. This is more
commonly encountered with bridge instruments.

This can be simple observed by rotating the meter movement quickly and
noting the deflection of the needle on the scale through inertia. An
undampened meter can be deflected by vigorous movement up to half
scale (possibly more), where a dampened meter would deflect barely a
tenth.

You got a bargain beyond dollars in your purchase.

Dave Heil <k8mn@frontiernet.net> wrote:

>There aren't any VHF digital TV signals.

Not today. But there will be, when the Big Switchover occurs. A significant number of stations which currently have their NTSC analog signals in the VHF range, and which have a temporary UHF allocation for their ATSC digital signals, will be moving the digital signals down to their VHF frequencies when the NTSC shutoff data occurs, rather than giving up the VHF frequency entirely.

There are a couple of reasons why this is being done. I believe that it adds up to "better digital coverage" - better antenna site, better transmitter, or (most commonly I think) a larger distance to the nearest competing station on that frequency. Some stations (especially in crowded urban areas) were stuck with UHF transition frequencies that have significant competition in nearby cities, and aren't allowed to transmit at full power... the band's pretty full.

Most of these stations have VHF allocations in the highband (channels 7 through 13). There are a very few stations in the VHF lowband (channels 2 through 6) which will be running ATSC digital in the lowband. but I'm told that this is being discouraged by the FCC and is technically less than ideal (more impulse-noise interference in the lowband).

In many areas of the country, a UHF-only antenna will prove adequate for ATSC reception.

In those areas in which one or more stations will be transmitting ATSC in the VHF band after The Day, an antenna with decent gain and directionality at both UHF and VHF will be necessary if you want to get all of the available channels. In most cases, UHF plus VHF highband will be adequate. A very few cities will require antennas that handle the VHF low-band as well. People jn these areas who have bought UHF-only "digital TV" antennas may be in for a rude shock.

The same designs that have been sold for decades (i.e. log-periodics with additional reflectors and elements for UHF) should work just

fine. A rotator may be useful or necessary.

The FCC's rulemaking document (latest version I know of) has a table
of the actual frequency allocations for DTV, including coverage areas
and interference levels:

http://hraunfoss.fcc.gov/edocs_public/attachmatch/FCC-06-150A1.pdf

Here in the Houston area there're three local stations broadcasting DT
in the VHF bands, one in the low band and two in the upper VHF band. The
other ten DT stations are in the UHF band, with Virtual broadcasts in
the upper end of their regular VHF channels. I'm not sure how that
works, but DT tuners can find them.

All will be UHF before the cut-off day in 2009.

According to "Reference Data for Radio Engineers", published by
International Telephone and Telegraph, fourth edition, page 35:

"Properties of Free Space"

Permeability = 1.257 * 10^-6 henry per meter.
Permittivity = 8.85 * 10^-12 farad per meter.

Characteristic impedance = sqrt(Permeability/Permittivity) = 376.7 ohms

I have one of those, or something very similar; a Struthers 1219-D.
The HF slug that came with mine goes up to 5kW, though. The meter
movement measures 24uA full scale, and the coil resistance is 2k ohms,
so the meter is pretty sensitive: about 1.1 microwatts for full scale
deflection. It takes that sort of sensitivity to get down to the
linear detector out versus RF power in region.

Interestingly, if I simulate a single-diode detector using an
HSMS-2850 Schottky diode into a 2000 ohm load, and find the RF voltage
that gives 24uA output, and then re-simulate with voltages in the
right ratios to give 90% of that power, 80%, 70%, etc., down to 10%,
the outputs are not exactly linear with input power. The error is
small, though, no more than about 1.5% of full scale. So then I
checked the calibration on my meter, and put in 50% of full scale

current, and noted that the meter reading is not exactly 50, but just enough off to be correctly reading the RF power. So though the scale on my meter appears at first glance to be linear, it's not exactly so, and I believe that must be intentional. The worst-case "error" to linear output in the simulation was at 70% of full power, where the current is predicted to be 71.43 percent of full scale. On my meter, when I put in 71.43% of full scale, indeed it reads almost dead-on 70% power. I doubt that's a fluke.

Cheers,
Tom

1840. 75M loop on 160

Newsgroup: rec.radio.amateur.antenna

Source record: 28512

On behalf of a friend, I am asking this question. He has a full wave 75M loop up about 40 feet, (247 feet of wire). He would like to somehow be able to "break" the far center of this loop to provide for half wave operation on 160.

He was thinking along the lines of some kind of choke or Hi-Z filter in the opposite leg that would electrically be open at 1950 KHz, and closed at 75M. I am dubious on doing this because of the extreme high voltages that would be present at this point... He runs a Kilowatt and feeds the loop with coax.

Is what he wants possible, either mechanically or electrically, without having to drop the antenna for manual switching?

To have a mind set around liquids and solids prevent true
understanding
of the elements and their magnetic fields which is the basis of all
the universe. If one thinks of H2O as being elements with a
electrical
field where the energy contained in that field determines the density
of like particles.
One way of looking at it is the transformation from ice to a gas with
each
transformation being ruled by the change in energy (latent energy)
One can simulate this action between a solid and a liquid by filling a
vessel with fine particles that is so dense that one cannot poke a
finger into it. When a gas (potentialenergy) is injected (now
kinetic)
into the bottom of the vessel the particles become liquid in form
such
that one can stir the contents in cluster form plus a pressure wave
in advance. Is it not a coincidence that 95% of elements are
diamagnetic
where the difference between that and paramagnetic is very small
and reflected in field strength or potential energy?

Absolutely. It's only relevant if the DTV channel happens to be on a widely
differing frequency where the "analogue" antenna is optimised for another
channel (= frequency).

Same as a different antenna for the CW part of a band (ie "CW" antenna)

>
> Yes, only the model I use substitutes a battery for the signal generator that you are using.

A battery is not the same since it has a very low output impedance.
A battery in series with a 50 ohm resistor would offer a reasonable
match to a 50 ohm transmission line.

> The returning wave can recharge the battery, but how does the current stop? Or does it ever stop? From a practical aspect, the current must stop, but I can not explain how except by resistance that absorbs the circulating power.

That is the challenging part to understand when too much emphasis
is placed on the existance of energy being transported with the
"reflected power".

When I was learning this stuff, I did many examples with matched
generators (a battery with a 50 ohm resistor is a good example).
With step functions, it is easy to compute the final state because
you can just treat it as a DC circuit for analysis.

> We must keep the limitations of our models in mind.

True, but over limiting is not good either.

> > When the generator is matched to the line so that

>
> > ...Keith
>
> The reflected wave that does not encounter an impedance at the generator must be on an

infinitely long line, and therefore the conditions must have changed between the time of launch and return.

I don't follow the association between generator impedance and length of line.

For a 50 ohm line, a matched generator has a 50 ohm output impedance. The returning wave does not encounter an impedance discontinuity so is not reflected. It disappears into the the generator.

> It makes more sense to think that the reflected voltage of (using your example) 50v meets 50v of forward voltage, and therefore finds an infinite resistance, coming to a stop.

The current does stop (since it can not flow into the infinite resistance at the end of the line), and a 50 V step propagates back along the line.

This 50 V reverse propagating step plus the 50 V already on the line produces a total of 100 V on the line.

If the generator was constructed as a 100 V battery in series with a 50 ohm resistor, then when the step arrives back at the generator, there is 100 V on both sides of the source resistor (battery on one side, line on the other) and the current through the source resistor becomes zero. No further current flows into the line.

> If that happens, doesn't the same condition occur as soon as the reflected wave is first generated at the line end? The current really stops as soon as the end is reached, with the energy contained in the magnetic field converted to electric field energy visible as voltage. If this happened, the reflected wave could be better described as an electric "jump", similar to a hydraulic jump found in open channel flow of liquids, where kinetic energy is converted to potential energy.

There do seem to be some similarities, though there is likely trouble if the analogy is carried to far.

> This idea of an electric "jump" requires not a reflection occuring without a discontinuity, but a moving wave front that absorbs the traveling wave, bringing it to a stop (in this case).

The current has stoppped, but has the "wave"?

Vf, Vr, If, Ir, Pf, Pr are still computable using the normal formulae.

Yes, I did get a great bargain. The meter came with a spring type wire
across the meter to short it out. I know this helps protect the meter
movement. Just have to remember to take it out when I want to use the
meter. Some of the old analog VOMs had an off position that did the same
thing.

Some of the Bird Hammate wattmeters had the very slow movements and Bird
would change them out for you.

1853. Wilkinson power splitter always necessary?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-02-02 23:28:57 UTC
From: "Francesco L." <franlanc@NOSPAMtin.it>
Message-ID: <60kcjaF1qrbfeU1@mid.individual.net>
Source record: 28525

I'm assembling a switch box for a 2 element vertical phased array. My idea is to create a system able to generate two alternate (and switchable) cardioids using a delay line (90°, 1/4 wavelength) and a two ways, two position relay in order to cover with an agle of 120° degrees one direction (e.g. North) or the other. As you all know, if two elements are fed in perfect phase the radiation pattern obtained is called broadside. This is exactly what I want to obtain introducing a second relay in order to get a third direction. At this point my question is: should I put a 10 w 100 ohm resistance (non inductive) between the two antennas (it's called Wilkinson power divider or power splitter) or the system works perfectly that way? There are two different school of thought: the first consider the wilkinson a must, since it lowers the swr and keeps it under control, the second school thinks it burns useful power and does not transfer all power.
So what's your point of view?
Thanks a lot in advance for your contribute

If the loads are equal and they are fed through equal lengths of line,
then a resistor between them (I assume you mean at the transmitter end
of the feed lines) will never dissipate any power, since it has equal
voltage at each end.

A Wilkinson splitter (or combiner) is used to provide isolation
between the loads, so that if one load is disconnected, the other load
still receives the same power. As a combiner, it isolates the sources
so that power from one source doesn't get into the other source; this

is very useful for combining generator outputs for intermod
testing...but it does depend on proper loading of the output port, and
it's only good at or near the design frequency.

Cheers,
Tom

Richard, what is the characteristic impedance of free space? There is only one answer, in Ohms. Since you are qualified to rise above the technical issues comment on this discussion, surely you can provide the correct answer. However, I was rather shocked that you may have seemed to agree with Roy that is was, um, 1 ohm??? Please Lord don't let it be true. Your groupies will once again be sorely disappointed.

Hint: it is greater than 1 and less than 400 ohms.

While you're at K7ITM, please give me your reference that the characteristic impedance of free space is, um, 1 Ohm as you stated in a preceding post.

Now a photon is not a particle? I would be interested in your description of the mechanism of the photoelectric effect.

I highly recommend reading the "Phased Array Techniqes" part of Chapter 8 of any edition of the _ARRL Antenna Book_ for about the past 15 or 20 years. It was first written not long after Dana Atchley popularized the use of the Wilkinson Divider for feeding phased arrays (and the error of which he later saw), so it contained quite a bit of detail about why that's a bad idea. When I re-wrote the section for the recent 21st Edition, I reduced the amount of material regarding the Wilkinson divider, since I thought it had finally faded away. I'm disappointed to hear that there's still a "school of thought" which regards it as a viable feed system after all these years.

If you have the 21st Edition, you'll find the complete text of the earlier material on the included CD. It contains more detail about why the Wilkinson divider isn't appropriate for this application.

Devoldere's _Low Band DXing_ also contains a lot of good information about phased array feed systems.

This is a humbling discussion!

Hadn't thought about it in terms of increasing the wave-length, but you are now messing with some of my basic assumptions about the universe with the obvious implication being its size and age. We might be able resurrects the steady state model!

Question: If photons are stable, chargeless, massless elementary particles, how do they react with anything?

Cheers

John, you're living proof, that, in some people, evolution is
a failure. Of course, you don't believe in evolution, which just
confirms the truth of the above statement. The question is, though:
Why do you bother to keep posting to a newsgroup where you are
universally loathed?

Hi Arend OM.
Thanks for your remarks. I had forgotten that the single coil Z match
could suffer from that problem, but of course you are quite correct.

Perhaps I might go back to the old 2 coil design yet!
All these queries are based on a very bad QRN problem my neigbouring Ham and I have had from power lines, even though our local lines are underground! So anything that keeps the sytem balanced is a potential help in hearing weak signals.
BTW I did try a 50 pF variable from feeder to ground as shown in the article I mentioned but it had little or no effect.

"Suzy",

I have learned through experience on this ng that people prefer that you post with your true call sign, name or email address. So I decided to do just that. Your anonymity generates this kind of response. I have already plonked the above two posters, both anonymous "John" and KA6RUH for reasons many consider obvious. Having said that, they are not generally offensive people and nobody will bother you here. People may contact you offline but it is OK and they will stay within the technical arena. I need not mention that the technical content of their posts is non-existent as usual. And I have had no problem with spam.

Follow up.

If the energy is lost over time (Not including the effect of acceleration)
by lengthening of the wavelength and by definition lowering the frequency I
would have thought this would be one the easiest theories to test. And as
far as I know there is no observations of radio signals changing frequency
due to distance by even the slightest degree.

I was thinking about this over lunch. Thanks Cecil!

I don't know of a broad-spectrum site (i.e. one which is multivendor)
other than general datasheet-search sites such as datasheetarchive.com

One good place to start looking would be at www.avagotech.com - I
believe that Avago Technologies is the current inheritor of the line
of RF Schottky diodes originally made by HP and then by Agilent. Some
of these parts are useful up to quite a few GHz.

Hello

Can anyone advise please. I have a new DAB tuner which works fine except the digital signal is not very strong around here. I am getting some 'popping' sounds as a result. The Bit Error Rate is about 0.04, less than the critical 0.05, but not brilliant. The indoor ariel supplied is 6 inches long. I have tried moving the indoor aerial around within the range of its cable with no real improvement.

Is there anyway of improving reception without installing an external aerial?

Thanks

KK

"Stable" doesn't mean they are inert. Photons are
emitted and absorbed all the time while interacting
with other particles. I believe Hecht means that
photons don't decay over time all by themselves
(but there is some debate on that subject).

Thank you, Richard, for pointing that out. As Perfect Tommy (Jeff Goldblum) said in Buckaroo Bonzai, "If it was a snake, it would have bit me". I've noticed the residue before, but never thought about it. I'll pass that on to our local VHF and up club, The NLRS.

Yes, that is correct about Avago. I believe I've come across diodes
there rated for use up to 40GHz, maybe 65GHz.

Also, look at other web sites (of companies with "new" names also!)
NXP used to be Philips. They definitely have some good RF detector
diodes. A Google search on "RF detector diode" just now turned up
several interesting hits, including some for sale on ebay. I saw
Vishay listed as an RF detector diode supplier, too, and I wasn't
aware they were really into that area--looks like they acquired
Telefunken, for another name change! But I suppose Suzy is looking
for non-surface-mount parts (from postings in another thread), and
that likely will be a problem for any new stuff. Pretty much
everything now has gone to tiny surface mount packages. -- OK, I
have to take that back. The Vishay web site has a kind of neat
feature and lets you look by package type--click on the picture of the
package. And it's real pictures, not line drawings. They DO have
glass axial lead RF diodes.

Cheers,
Tom

Hello,

I am not a specialist in relativity. The EM shock wave generated by
the particle with rest mass (for example electron) entering a medium
with c < v(particle) contains energy, but as far as I know, the photon
has no rest mass, it carries momentum. It can therefore exert a force
on an object (radiation pressure in classic electromagnetic theory).

Best regards,

Wim

> Looking for a website that gives comparative performance of diodes (max
> frequency for UHF use)

Hello Suzy,

The type of diode that will be best for your application depends on
the type of application.

For high level detectors (above several volts of RF input power), the
BAT62 is a good one up to some GHz. It has low capacitance (at Vj=0V)
and a reverse voltage of 40 V (fourty V). You cannot use it in low
noise mixers because of high intrinsic resistance.

Most of the HP or equivalent "hybrid" Shottky detector diodes (with
70V reverse rating) have far higher capacitance then the BAT62. Check
the datasheets, the 70V diodes are measured at Vj = -0.5V. At Vj=0V,
capacitance will be >> 1pF. For mixers, the best are the pure Shottky
rectifiers (that have a reverse voltage of less then 4..6V). For
Zero IF systems (Doppler radar, movement detection), other type of
shottky diodes are used (with low 1/f noise).

When you want to make a (calibrated) low level RF detector (for RF
levels < 10mV), you need to consider the so-called "video
resistance" (that is the differential resistance of the diode at 0V
bias). To get full benefit of a low level detector, the DC voltmeter
(or buffer amplifier) must have a Rin >> video resistance. Otherwise
you cannot convert the DC voltage back to an RF input voltage.

The video resistance varies from about 10 kOhm (special "zero bias"
detector diodes) to several Mohm (for high barrier mixer diodes). Main
advantage of zero bias detector circuit is that you do not need to
build a temperature compensation (for compensating the about 2mV/degr.
C).

For UHF mixer or low level detection I use BAT15 (Cj < 0.35pF at
Vj=0V).

Best regards,

Wim

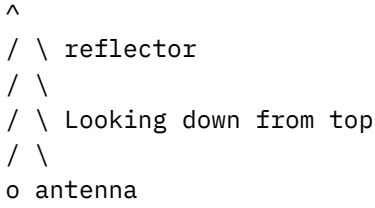
You could try sticking a bit of aluminium (aluminum) foil to the card from a cereal packet. Fold the cardboard to form a right angle and stand it with the folded edge vertical near to the antenna to form a reflector. Adjust for best signal strength. For a 6 inch antenna, the card only needs to be the size of an A4 sheet of paper, around 8 inches by 12 inches. Fold in half so that you have two surfaces at 90 degrees to each other, 8 inches by 6 inches.



If this doesn't work, you need a bigger antenna.

Thanks a lot to both of you. I have the two books mentioned above and I did not suspect the cd rom contained all the former articles published. I did not use it since the programs on the cd did not install on my pc ;-) About the Low band dxing, it is very very complicate for a beginner like me and even if I wrote to the author in order to get more info, he never replied. So I'm gonna have a deep look at the ARRL cd and also trusting what you summarized! I've also found a leaflet (published online in pdf) by HyGain where they suggest different combinations of phased arrays which use their verticals and there are no schemes containing the resistor.
I asked since an Italian dxer (i4ewh) in its scheme considers this splitter absolutely necessary. I spoke with him and he told me the swr was greatly reduced by this solution. Anyway here is the link so you can have a look. It's a four element phased array:
http://i4ewh.altervista.org/ShortWaves/Verticali_file/Verticali.htm
Once again, I must repeat that low band dxing has no help for beginners and better and simpler schemes can be found on the simple "vertical antennas" by arrl and arrl antenna book. If you have any other site or web address where I can find more material, please tell me.
A last question to both of you: I would like to use this system (centered for the 20 meters band) also for 40 meters and 10 meters. Should an antenna tuner suffice?

I understand red-shift in terms of astronomy, but you can never be sure of all the effect in that situation such as acceleration and gravity. I suggest that there is no observations of radio signals changing frequency due to distance under lab conditions, which I still believe would be a relatively easy test.

I agree with what you say above although I am not sure what an EM shock wave is. It is the terminology. If the electron(s) moving through a medium such as free space in a time varying field, then photons (radiation) is generated in accordance with Maxwell's laws. I assume you made a typo when you say c<v; you meant v<c.

This, from an alleged guru who has been able to rewrite quantum theory and disprove maxwell planc and Neils Bohr and state that a photon is not a particle. He claims he can follow a discussion and actually follow a thread with Richard Clark involved in it? All this is happening whilst Richard C. is still trying to sort out how RF EM waves and acoustic sound waves interact with each other. Of course, all this is going on with neither knowing what the characteristic impedance of free space is or what it implies. I need to make the following reality check: This group is entitle rec.radio.AMATEUR.antenna so discussing technical issues with these two is akin to discussing evolution theory with the late Jerry Falwell. Still I find it quite amazing.

Richard, per your comment above you agree then to the possibility of a case where the v>c. Tell me, what kind of particle or wave can have a velocity faster than the speed of light? Perhaps you are discussing tachyons? ;-) Do you believe in universal constants such as the speed of light?

Okay, Tom, good to hear that. First thing of course is to get the
General license.

Second thing is that HF is a whole different animal than VHF. My
experience with new guys and gals is that they often think of HF/MF as
just another set of frequencies to use. It is and it isn't. Propagation
knowledge is needed, not only on your end of the signal, but on the other
end as well. Working the vagaries of propagation is one of the great joys
of Ham radio, but it requires a pretty big commitment, and an enjoyment
of the game as well. You're going to have to get on the air, and spend a
couple years learning - it isn't going to be like using a computer
program.

HF is an unruly beast, and your antenna is only going to be a small part
of it.

I'm not trying to bust your chops here, it's just a different ball game,
and your post started out like one of those "just tell me what I need to
do" commercials. 8^)

> What I was hoping to find was operators who have already used one or
> more of the antennas I was asking about who would be willing to share
> their experience of the effectiveness or lack of same with me.

My vote is for the general purpose dipole and a tuner. Flexible,
and "all HF band". It will work in multiple locations, (important for an
antenna that must be raised in whatever condx are present) is reasonably
efficient, and works pretty darn well.

Oh, crap, Daniel. Roy did not say free space was = 1 ohm. Look back and
read:

You said:
"> I should say "characteristic" impedance is 377 Ohms. It also has a
> permitivity and permeability of 1 ;-) "

Roy said:
"I'm sure you mean relative permittivity and relative permeability.

The characteristic impedance is the square root of permeability divided
by permittivity, so if both are one, the characteristic impedance would

have to be one."

Get it? He is saying that the permeability and the permittivity of space can not = 1 because if they were, then the intrinsic impedance of space would be = 1 because the intrinsic impedance of space is actually Zo = sqrt(permeability/permittivity).

The correct values were posted earlier in this thread. You can verify them for yourself using your favorite source. But don't confuse them with relative permeability/permittivity.

John

It is clearly possible for certain events to happen at speeds greater than the speed of light in a vacuum, or any other material for that matter. It is relatively trivial to accelerate electrons and other charged atomic particles to speeds approaching the speed of light (in a vacuum). If the particles in two such beams are collided head on, clearly the impact velocity will be something just below 600,000 Km per second, or just under twice the speed of light.

The resulting atomic debris and energy generated in such collisions are keenly studied by physicists eager to probe the limits of physical science. Neither set of particles are exceeding the speed of light and yet any collisions must take place at velocities greater than the speed of light. The speed of light is a fundamental physical limit against which other phenomena may be measured. It is not necessarily a barrier which cannot be exceeded under any circumstances. There is ample experimental evidence to suggest that faster than light phenomena do exist. The most compelling evidence to date coming from experiments involving entangled particles and quantum encryption techniques.

Well, he is correct, you were wrong with your SQRT(1/1) = Zo = 1. If you use his values, you will get the proper value (377 Ohms) so he is correct. Glad you finally saw the light.

True, but these "events" would not include travelling 3 X 10E8 meyers in
less than one second.

Well, not trivial but possible. It happens in nature with mu-mesons (cosmic
rays). But you were careful to say "approaching" the speed of light.

> If the particles in two such beams are collided head on, clearly the
> impact velocity will be something just below 600,000 Km per second, or

Have you ever read about the theory of relativity? GONG! The speed of each
beam relative to the other is still 3 X 10E8 meters/sec. Sorry but you just
betrayed your lack of knowledge of that theory. Einstien disprovedwhat you
said in 1905 but take comfort in the fact that it was difficult to
comprehend at the time. The speed of liht relative to any reference point is

a universal constant, c = 3 X 10E8.

When I review the content which you quote from me (complete to all my statements), yes it appears that I said that. Those two words would seem to be terse enough not to be equivocal. Question is, having offered it twice now, are you going to ask me again if I said it?

And specifically, it is not a "possibility" such that it is arguable, it is a certainty. Also within the quote above is a very common instance cited that can be easily verified or rejected on the basis of fact - if you check facts that is.

This topic must be in the scope of your earlier claim about taking me head to head on Physics and emerging best. A poor fool such as I with a simple English degree should be easy to champion over. You should be able to re-parse your earlier question into a match draw. If not, read more Cecil to refine your technique.

Come on Richard, you know your groupies will be ever loyal. Either you dragged him down to the level of Pee Wee Herman, or he dragged you down from Shakespeare to that level. Something tells me it was the former but you then rub salt in that wound by positive reinforcement. Could this be considered groupie abuse? ;-)

Hi Roy!

I've been away from the list for a few months, and I've been catching up the last few days. Who is this new whacko? Is he Art with a different name? I'm guessing no, since his style of attack is much more primitive, but I had to ask. He is kind of funny in a weird way, but I'm guessing that wears off quickly.

Hope you've been well.

The particles exit the radioactive substance at just a smidge less than
c in a vacuum, and enter water which has a value of c much lower than c
in a vacuum. They then produce a wonderful blue glow because they are
breaking the speed limit.

Here is a page with a relatively simple explanation

http://en.wikipedia.org/wiki/Cherenkov_radiation

I breathlessly await your response.

>
>

While the speed of each beam relative to a stationary observer is 300,000 Km/s with both beams travelling in opposite directions, the combined velocity relative to that stationary observer is 600,000 Km/s. Einstein did state that from the point of view of someone or something travelling with the beam the combined velocity of the two beams approaching collision would appear to be 300,000 Km/s. Einstein was wrong on this point because for a wavefront or beam propagating at the speed of light, no time passes and therefore no velocity measurement is possible or has any meaning in conventional terms. Clearly we are wasting a lot of time, effort and money in bothering to build bigger particle accelerators (like at CERN) if the combined collision velocities can never exceed 300,000 Km/s.

Einstein (who is greatly over rated in my opinion) got a lot of stuff right, but there are some pretty huge gaps in the theory, particularly where values tend towards infinity. Hence the inability to deal with gravity, a failure of the theory in dealing with black holes and an inability to deal with super luminal velocities. Richard Feynman was a far better theoretical physicist who actually invented ways of reconciling and sidestepping some of the paradoxes inherent in Einstein's equations.

Just as Einstein refined Newton's ideas, future physicists will regard Einstein's theories the way we regard Newton's; a good approximation for everyday use, but not a true description of the processes. How on earth did NASA get astronauts to the moon using just Newtonian mechanics? The mind boggles. :-)

Oh, crap, Daniel!

No! He said, "...if both are one, the characteristic impedance would have to be one." He is saying that, if what YOU say is true (the permittivity and permeability of free space is one), then that would force the Zo of free space to one because Zo = sqrt(permeability/permittivity).

Note that he said IF. Pay attention!

No, YOU'RE the one who said it is one. You are the one who said the permittivity and permeability of free space = 1 (go read and understand your own post). Now plug your ones into: Zo = sqrt(permeability/permittivity).

No, I only asked if you agreed to the possibility of FTL travel of waves or particles (faster than light). I was not asking if you "said" anything. You appear to agree to the possibility that the universal constant c can be exceeded, at least in nuclear cooling pools. .

>
> And specifically, it is not a "possibility" such that it is arguable,

There you go. A good crisp position! Indeed, you believe FTL travel is commonplace at least for some waves and particles.

> Also within the quote above is a very common
> instance cited that can be easily verified or rejected on the basis of
> fact - if you check facts that is.

I do not believe that any wave or any particle can exceed the speed of light. FTL only happens in the X-Files but that is the opinion of a mere engineer. In this area, I am definitely caught in the past. When t prime = t ref/SQRT(1 - v**2/c**2), i.e. the lorentz transformation/time dilation, becomes negative due to v being greater than c, I run into all these problems of past events possibily affecting present events resulting in all sorts of paradoxes that are impossible to resolve through logic. I am too old and too attached to Einstein's theory of General relativity to "Check the facts" as you suggest. I will be led down a black hole (without ever exceeding c as I approach the center ;-)) You are beyond Einstein's "theory", you have upgraded to "fact" and negative time. Wow. Just the same, the probability that I might find something (other than "tachyons" ;-))

that moves faster than light remains to me to be very small. Sorry but it is not worth the effort. I will continue to adhere to my primitive belief system which holds that no wave or particle can exceed 3 X 10E8 (in a vacuum if you will).
>

I actually minored in English. When one participates in a baccalaureate degree program at an actual "university", the BS curriculum requires a minor in the arts. This means I understand to some degree where you are coming from. I never made an ad hominem attack on your arts capabilities as you did my physics capabilities. I contend that you were not qualified to make that judgement based only upon my being an engineer and not knowing which university issued the degree or indeed if it was a university that issued the degree (as opposed to an engineering "college").

English literarure was fun; it was a nice form of recreation and an easy ACE for 20 of my 140 credits.

A recollection from decades back are the 1N21, 1N23, 1N32, 1N53, 1N60, and 1N78 point-contact silicon diodes that were used as mixers well into the microwave spectrum. Googling 1N23 produces 8000+ hits... including a "Simple 2.4 GHz SWR Meter": (http://www.qsl.net/n9zia/24swr/index.html). I see RF Parts (http://www.rfparts.com/) sells the 1N21 and 1N23. MicroMetrics (http://www.micrometrics.com/) makes them, as well as various schottky diodes suitable for sampling.

Not true. The observer on light beam 1 is experiencing time in his own frame of reference. As far as he is concerned, he is not moving. He experiences normal time in his frame of reference. And, he sees light beam 2 coming to him at 3 X 10E8 meters/sec.

>Clearly we are wasting a lot of time, effort and money in bothering to

They are NOT attempting to exceed 3 X 10E8 meters/second!
>

For the purpose of this discussion he got EVERYTHING right and his theories have been proven time and time again.

> sidestepping some of the paradoxes inherent in Einstein's equations.

A black hole is not a paradox. It is simply enough mass such that its escape velocity from its huge gravitational filed is greater than the speed of light. What is so paradoxical about that? The only paradoxes that arise in Einstein's equations occur when people make assumptions that certain universal constants like the speed of light can become variables and then the ridiculous paradoxes start to occur. If we try to change the constant pi, wouldn't we get a lot of unrealistic calculations? Changing the value of c is the same as trying to change pi.

>

Maybe in 100 years or so. We are not even close to such a refinement right
now. Maybe we never will be.

> How on earth did NASA get astronauts to the moon using just Newtonian
> >mechanics? The mind boggles. :-)

The moon is only 450,000 miles away. All velocities, distances and times
involved in a trip to the moon, or Mars, are as Newtonian as a trip on a jet
from London to New York. :-)

Although I don't consider myself a "groupie" of Richard's, I do read all his post's because I find him very entertaining - in the best sense of the word - his wit is probably the best in the group, if sometimes acerbic.

Perhaps Pee-Wee Herman is a bit pedestrian for your tastes, so here is another one for you.

"We don't receive wisdom; we must discover it for ourselves after a journey that no one can take for us or spare us."

Most fitting, and you certainly know the source, don't you?

And for what it is worth, the IQ here is measured out at 150. Let me know if that is enough. If I'm not smart enough, or not technical enough for you, please feel free to filter my messages.

So, this is the third time I have to point out that two words were
unequivocal? As one of my groupies, you are the most devoted follower
of my posts currently.

>I do not believe that any wave or any particle can exceed the speed of
>light.

That is clearly evident.

>I am too
>old and too attached to Einstein's theory of General relativity to "Check
>the facts" as you suggest.

Again, clearly evident. You are standing on the wrong street corner
for this parade.

>I actually minored in English. When one participates in a baccalaureate
>degree program at an actual "university", the BS curriculum requires a minor
>in the arts. This means I understand to some degree where you are coming
>from.

20 hours on your minor are not evident - not even by degree. Let's
perform some simple deconstruction on
"You appear to agree to the possibility..."
in response to an explicit and unequivocal:
"It is most common and evident
(meaning you can trust your eyes this time)
in cooling water pools for nuclear reactors."
Parentheticals aside, my two sentences and fifteen words are re-cast
into terms of "appear" and "possibility" where your ambiguous
interpretative paragraph (not completely quoted above) is longer than
the direct statement.

>I never made an ad hominem attack on your arts capabilities as you did
>my physics capabilities.

Yes, I know and it keeps me awake on these long winter nights. As you
yourself put it, I disappoint my groupies, don't I? You can add your
minor as a victim of ad hominem atrocities - I will have to make up
for it by sleeping in later in the mornings.

> current through the source resistor becomes zero. No further
> current flows into the line.
>
> > If that happens, doesn't the same condition occur as soon as the reflected wave is first generated at the line end? The current really stops as soon as the end is reached, with the energy contained in the magnetic field converted to electric field energy visible as voltage. If this happened, the reflected wave could be better described as an electric "jump", similar to a hydraulic jump found in open channel flow of liquids, where kinetic energy is converted to potential energy.
>
> There do seem to be some similarities, though there is likely

Here is a link to a web site discussing reflections and more.

http://www.ivorcatt.co.uk/em.htm

He has some drawings that pertain to this discussion. He shows reflections and crossings, but no one-way transmission lines.

Only 150? Ahaha! Inferiority complex!

Mind you... could be worse... Did you know that at the last count nearly
half the population had less than the average IQ?

Definition: Ad hominem - attacking the arguer and not the argument

Now, whatever could ever dispose one to do that, a technique he freely admits to? Intellectual insecurity? It is an atrocity merely commited upon one's self and reputation but I doubt it really affects your somnolence after all these years.

I just love this quote from that material "...Thus do these clapped-out
radio men..."

Though it's all above my head, I have indeed met some clapped out radio men.

The SWR has nothing to do with the antenna pattern. A good SWR can be had with a feed system which produces a lousy pattern, and obtaining a good pattern can result in a poor feedpoint SWR. But the feedpoint impedance is easily fixed with a matching network. A poor pattern is much harder to correct.

Anyway here is the link so you can have a look.
> It's a four element phased array:
> http://i4ewh.altervista.org/ShortWaves/Verticali_file/Verticali.htm

It's entirely possible that this arrangement does produce some nulls and peaks. But it almost certainly isn't producing the pattern that the author thinks and, if the resistors are doing anything at all, they're wasting power which could be radiated. The _Antenna Book_ explains why.

> I can find more material, please tell me.

There's a great deal of information about phased arrays in books and on the web. I haven't done a comprehensive survey, but would guess that a solid majority is wrong. And if you're not pretty well aware of the basic principles and problems of feeding phased arrays, you probably won't be able to tell which is and which isn't. Look over the _Antenna Book_ information, both in the 21st Edition and the material from the 20th which is on the CD. If you find it too hard to understand, drop me an email.

> A last question to both of you: I would like to use this system (centered

> tuner suffice?
> Francesco ik8vwa

No. All an antenna tuner does is transform the feedpoint impedance. It does nothing to produce the element currents you need in order to get the pattern you want. It is possible to make a reasonably good multi-band receiving array as long as it's electrically small. (An HF receiving antenna doesn't have to be efficient.) But to make a decent transmitting phased array for multiple bands usually requires a separate

feed system for each band, and probably separate elements for each band also. You can, of course, use any of a number of simple feed systems on multiple bands which will give peaks in some directions and nulls in others. But the patterns won't be anything like the textbook patterns for properly fed arrays.

I was and still I'm conscious of this but my question was different
and maybe not so well expressed, so excuse me and read this please:
my intention is to use the two antennas also to radiate in the 7 mhz
band (spacing in this case would be 1/8 and the radiation lobe almost
omnidirectional) and 28 mhz (spacing would be 1/2 wavelength and the
radiation pattern should be end-fire). This is because the system
would be designed for the 20 meters band with 1/4 wave spacing between
the two elements, but as you know, that spacing corresponds to 1/8 and
1/2 respectively in the 40 and 10 meters band. I know the sensitivity
should not be the best but using an antenna tuner I think the
radiation patterns should be as predicted before, what do you think?

Last time I checked the moon was somewhat nearer to 250,000 miles away :-)

For an observer travelling at the speed of light, all distances effectively disappear and become equal. For that observer it appears to take the same time to travel to Alpha Centuri or to the Andromeda Galaxy. In fact the observer would have no sensation of time whatsoever. From our external view point, the respective journeys would take four years and several million years. This is one of the crucial failures when interpreting Einstein's theory. Time for something or someone travelling at the speed of light ceases to exist as does the concept of distance. In order for the theory of relativity to work it is necessary to have some constant against which to guage the effects. The speed of light in a vacuum is a very reliable and convenient constant. It does vary considerably in other mediums though which implies it is not the gold standard of velocity measurement, just the best we have at the moment. In fact, the theory of relativity implies that there cannot ever be an absolute standard against which to measure anything.

My interpretation is that the speed of light is not some insurmountable barrier, just a point at which conventional theory hits a brick wall and is unable to deal with what lies beyond. The same was true of aerodynamic theory up to the 1940's with respect to the sound barrier, even though projectiles fired from rifles and large artillery pieces were known to exceed the speed of sound. Once Chuck Yeager broke the sound barrier, aerodynamic theory had to be expanded. It didn't mean that everything that went before was wrong, just that it could not be used to make predictions for flight at speeds greater than the speed of sound.

The speed of light in a vacuum is currently the constant at which present theory breaks down and yet particles have been observed travelling in a manner that can only be explained if it is assumed they have moved from one

point to another at speeds greater than the speed of light.

It may well be that wave-particle duality breaks down at the speed of light and that only a particle can exceed light speed. The absence of waves means that it's presence cannot be detected and it effectively drops out of our perception until the speed drops back to sub-light velocities.

If I could find a local source, I wouldn't mind too much on missing
out on the homebrewing :-).

But the gotcha here is that I think that what Cecil pointed to on the
Wireman website is window line, not ladder line. And after reading the
comments here I'm pretty sure that it's the webbing in the window line
that causes all the wind load, so that's not what I want.

I have worked with the stranded-copper-clad-steel wires on antenna
projects and they really are a breeze to work with. Not difficult at
all!

#18AWG solid copperweld is manageable... it's got a pretty good memory
of past curls but it doesn't take a lot of tension to make it forget.
#14AWG solid copperweld or bigger... yes, that's a chore to work with
just one conductor, and if I tried two at a time you would find me
wrapped up in a horrible twisted tangle of the stuff.

I do have a local source for stranded-copper-clad-steel and can
certainly homebrew my own insulators. Looks like the way to go!
Although the work of assembling it all makes it sound like it'll take
most of a weekend.

It's easy to get the correct phasing with two identical elements which are in phase or 180 degrees out of phase -- you simply feed them with equal lengths of coax (in phase) or lengths which differ by 1/2 wavelength (out of phase). Alternatively, you can use a reversing transformer for the out of phase case. You can also use other odd multiples of 1/2 wavelength although the beam and SWR bandwidth gets narrower as you use longer lengths. So as long as you create a feed system which does this on every band, you'll be fine.

The problem is in making the 90 degree phased array on 20, which I recall you wanted to do. (If not, disregard the rest.) The feed system for that pattern will work only on the one band, so you'll have to switch it out on the other bands. The L network feed systems described in the _Antenna Book_ use equal length lines plus an L network for doing 90 degree feeds. So you could use the L network on 20, and switch it out but use the same feedlines for the other bands to get two in-phase elements on those other bands. You would need a tuner, though, since the impedance at the common feed point will be different on each band.

It all depends on the fineness of the tool. Present measurement techniques do indeed have most people at that statistical "average intelligence". But I liken it to using a meter that has only 10 volt increments. A lot of different voltages can be covered in gross increments like that.

I do know the source but question its relationship to rraa.

>
> And for what it is worth, the IQ here is measured out at 150.

I know. Almost EVERYONE here claims to have a superior IQ and I will
say further that I could never claim an IQ that high niether could
0.01% of the population in the world. It just seems odd to me that so
many high IQ people gravitate to rraa. So much brain power all in one
place!

Certainly you are a MENSA member. What is your MENSA number if I may
ask?

In truth, I think there is only one or perhaps two people in this
group who really do have such abilities, one is a MENSA member and you
can tell by the quality of his posts. The other is the one who is
actually capable of challenging him and does so on a regular basis.
Meanwhile I shall be happy with my measly 135, which is still enough
to sort through the regular BS I see here.

Let me know
> if that is enough. If I'm not smart enough, or not technical enough for

Smart enough? YOU are the on with the 150 IQ! I am not even
intellectually endowed withenough brain power to achieve a PhD. You

could replace Steven Hawking as the Dean of Physics at Cambridge!

Re HDTV. It would seem there are at least 2 boondoggles going on.

1. Cable and satellite providers claim they are carrying local HD channels. But what they don't say is that most local digital stations have multiple digital programs (One of my locals has 5), and only ONE of those is usually carried by the mass providers. The only way to get the rest is with a local antenna.

2. It is easily possible to distribute SD TV signals throughout your house using an NTSC modulator and coax cable. But you can't do that with HD TV, because the MPAA has made it impossible to buy the required ATSC modulator. I wonder how long that restriction will survive after analog TV goes away?

Dan's a nice enough guy, Richard, but some times a little slow on the uptake (witness the consternation over my "speed of dark comment a while back - honest, it was a joke 8^) I think it causes some misunderstanding at times. Maybe if we just gave a little extra time?

Possession of a high IQ is merely a gift, a talent as it were, not tremendously different than the ability to play a musical instrument well, to create art, or a fine physical shape for that matter.

What we do with it is what counts. I know people with higher IQ's than mine who are worthless, and I know some people who were in special education classes in high school who became degreed - admittedly not in

a science field, but they got the scroll. I have much respect for the
latter.

Source record: 28386

After 60 years of operating from Dutch soil, Radio Netherlands
shortwave has left the country seeking better (cheaper) propagation
outlets to serve their listeners. For hamradio there was an unique
opportunity to use the idle antennas. PA3GVI had such an opportunity
his small hamradio next to the 500kW big brother connected to
curtainantennas of 22dB gain. In practice the 100W of the trx, gave
him an ERP of 8kW. The low angle of the system gave him an ease to
work other hams working on a broomestick at the other and of the
world.
He uploaded on YouTube the following teaser:
http://nl.youtube.com/watch?v=3vE1zk60v3E
Thanks to the original poster (Joop!) from Dutch hamradio usenetgroup.

> waves.

Your suspicion is quite incorrect. Real-world generators
which present well defined impedances to the reflected
wave are common.

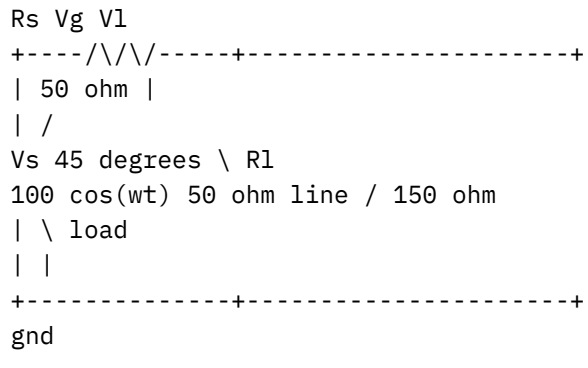
And your assertion that a lack of reflections will
result in a violation of the conservation of energy
principle is also incorrect.

The equations you present above hold just as well
when there is no reflection at the source.

It might do to analyze a simple example. To simplify
analysis, this example does use ideal components:
there is an ideal 50 ohm transmission line (R=G=0,
uniform 50 ohm impedance along its length), two
ideal resistors (zero tempco, no inductance or
capacitance, just resistance), and an ideal voltage
source (desired voltage is produced regardless of
load impedance, though the external components mean
this source does not need to provide or sink infinite
current).

If you don't think any understanding can be gained
from examples with ideal components, please read
no further.

This simple example has a voltage source in series
with a 50 ohm resistor, driving 45 degrees of 50
ohm line connected to a 150 ohm load.



The voltage source in series with the 50 ohm
resistor forms a generator.

Vs(t) = 100 cos(wt)

or, in phasor notation

Vs = 100 /_ 0d

where d is degrees or 2*pi/360 when converting to radians
is appropriate.

When the source is turned on, a wave travels down the
line. At the generator terminal (Vg), the forward voltage
is:
Vf.g(t) = 50 cos(wt)
Vf.g = 50 /_ 0d
since the voltage divided evenly between the source
50 ohm resistor and 50 ohm impedance of the line.

At the load, the voltage reflection coefficient is

RCvl = (150-50)/(150+50)
= 0.5

The forward voltage at the load is

Vf.l(t) = 50 cos(wt - 45d)
Vf.l = 50 /_ -45d

The reflected voltage at the load is

Vr.l(t) = 0.5 * 50 cos(wt - 45d)
= 25 cos(wt - 45d)
Vr.l = 25 /_ -45d

The voltage at the load is

Vl = Vf.l + Vr.l
= 50 /_ -45d + 25 /_ -45d
= 75 /_ -45d

Vl(t) = 75 cos(wt - 45d)

At the generator, the voltage reflection coefficient is

RCvg = (50-50)/(50+50)
= 0

so there is no reflection and the system has settled
after one round trip.

The voltage at the generator is, therefore,

Vg = Vf.g + Vr.g
= 50 /_ 0d + 25 /_ (-45d -45d)
= 50 /_ 0d + 25 /_ -90d
= 55.902 /_ -26.565d
Vg(t) = 55.902 cos(wt - 26.565d)

Currents can be similar computed...

If.g(t) = 1 cos(wt)
If.g = 1 /_ 0d

RCil = -(150-50)/(150+50)
= -0.5

If.l(t) = 1 cos(wt - 45d)
If.l = 1 /_ -45d

Ir.l(t) = -0.5 * 1 cos(wt - 45d)
= -0.5 cos(wt - 45d)
Ir.l = -0.5 /_ -45d

Il = If.l + Ir.l
= 1 /_ -45d - 0.5 /_ -45d
= 0.5 /_ -45d
Il(t) = 0.5 cos(wt - 45d)

And just to check, from V = I*R
R = V / I
= Vl(t) / Il(t)
= (75 cos(wt-45d)) / (0.5 cos(wt-45d))
= 150
as expected.

RCig = -(50-50)/(50+50)
= 0

Ig = If.g + Ir.g
= 1 /_ 0d - 0.5 /_ (-45d -45d)
= 1 /_ 0d -0.5 /_ -90d
= 1.118 /_ 26.565d
Ig(t) = 1.118 cos(wt + 26.565d)

Now let us see if all the energy flows balance properly.

The power applied to the load resistor is

Pl(t) = Vl(t) * Il(t)
= 75 cos(wt - 45d) * 0.5 cos(wt - 45d)

Recalling the relation
cos(a) * cos(b) = 0.5(cos(a+b)+cos(a-b))

Pl(t) = 75 * 0.5 * 0.5 (cos(2wt-90d)+cos(0))
= 18.75 cos(2wt-90d) + 18.75 cos(0)
= 18.75 cos(2wt-90d) + 18.75

Since the average of cos is 0, the average power is

Pl.avg = 18.75

To confirm, let us compute using

Pavg = Vrms * Irms * cos(theta)

Pl.avg = (75 * 0.707) * (0.5 * 0.707) * cos(-45d-(-45d))
= 18.75 * 1
= 18.75

Agreement.

Now at the generator end

Pg(t) = Vg(t) * Ig(t)
= 55.902 cos(wt - 26.565d) * 1.118 cos(wt + 26.565d)
= 55.902 * 1.118 * 0.5 (cos(2wt)+cos(-53.130))
= 31.249 cos(2wt) + 31.249 * 0.6
= 31.249 cos(2wt) + 18.75
Pg.avg = 18.75

Good news, the average power into the line is equal to
the average power delivered to the load, as required to
achieve conservation of energy.

Now let us check Pf and Pr

Pf.avg = Vfrms^2 / Zo
= (50*.707)^2 / 50
= 25

Pr.avg = Vrrms^2 / Zo
= (25*.707)^2 / 50
= 6.25

Pnet.avg = Pf.avg - Pr.avg
= 25 - 6.25
= 18.75

Again, as expected, the average energy flow in the line
is equal to the average power into the line and the average
power out of the line.

So, contrary to Cecil's assertion, an analysis based on
'no reflections at the source', has not resulted in any
violation of conservation of energy. This is good.

It is instructive to continue the cross-checking.
Let us validate the input impedance of the line.

Using a Smith chart, and going towards the source from
a 150 ohm load on a 50 ohm line yields

Zin.smith = 30 - j40
= 50 /_ -53.130

Dividing the voltage by the current at the input to the
line...

Zin = Vg / Ig
= 55.902 /_ -26.565d / 1.118 /_ 26.565d
= 50.002 /_ -53.130
= 30.001 -j 40.001

yields the same result as the Smith chart.

Lastly let's compute the power provided by the source...

Ps(t) = Vs(t) * Is(t)
= 100 cos(wt) * 1.118 cos(wt+26.565)
= 111.8 * 0.5 (cos(2wt+26.565) + cos(-26.565))
= 55.9 cos(2wt + 26.565) + 55.9 * 0.894
= 55.9 cos(2wt + 26.565) + 49.999

Ps.avg = 49.999

and that dissipated in the source resistor

Prs(t) = Vrs(t) * Irs(t)
= (Vs(t)-Vg(t)) * Ig(t)
= (100 cos(wt) - 55.902 cos(wt - 26.565d)) * 1.118 cos(wt +
26.565d)
= 55.902 cos(wt + 26.565d) * 1.118 cos(wt + 26.565d)
= 55.902 * 1.118 * 0.5 (cos(2wt + 53.130) + cos(0))
= 31.249 cos(2wt + 53.130d) + 31.249

Prs.avg = 31.249

The power provided by the source is equal
to the power dissipated in the source resistor and the
power dissipated in the load resistor.

49.999 = 31.249 + 18.75

So all the energy is accounted for, as expected.

When the source impedance is the same as the line
impedance, there are no reflections at the source
and all the energy is properly accounted. There is

no violation of the conservation of energy principle.

...Keith

PS. It is worthwhile to note that there are a large number (infinite) of source voltage and source resistor combinations that will produce exactly the same final conditions on the line. But if the source resistor is not 50 ohms, then there will be reflections at the source and it will take infinite time for the line to settle to its final state.

I find, then, this great and numerous people, sprung from a single man, who worship one God and guide themselves by a law which they say that they obtained from His own hand. They maintain that they are the only people in the world to whom God has revealed His mysteries; that all men are corrupt and in disgrace with God; that they are all abandoned to their senses and their own imagination, whence come the strange errors and continual changes which happen among them, both of religions and of morals, whereas they themselves remain firm in their conduct; but that God will not leave other nations in this darkness for ever; that there will come a Saviour for all; that they are in the world to announce Him to men; that they are expressly formed to be forerunners and heralds of this great event and to summon all nations to join with them in the expectation of this Saviour.

To meet with this people is astonishing to me, and seems to me worthy of attention. I look at the law which they boast of having obtained from God, and I find it admirable. It is the first law of all and is of such a kind that, even before the term law was in currency among the Greeks, it had, for nearly a thousand years earlier, been uninterruptedly acc

the Jesuits and Jansenists are wrong in concealing them, but the Jansenists more so, for the Jesuits have better made profession of the two.

866. Two kinds of people make things equal to one another, as feasts to working days, Christians to priests, all things among them, etc. And hence the one party conclude that what is then bad for priests is also so for Christians, and the other that what is not bad for Christians is lawful for priests.

867. If the ancient Church was in error, the Church is fallen. If she should be in error to-day, it is not the same thing; for she has always the superior maxim of tradition from the hand of the ancient Church; and so this submission and this conformity to the ancient Church prevail and correct all. But the ancient Church did not assume the future Church and did not consider her, as we assume and consider the ancient.

868. That which hinders us in comparing what formerly occurred in the Church with what we see there now is that we generally look upon Saint Athanasius, Saint Theresa, and the rest, as crowned with glory and acting towards us as gods. Now that time has cleared up things, it does so appear. But at the time when he was persecuted, this great saint was a man called Athanasius; and Saint Theresa was a nun. "Elias was a man subject to like passions as we are," says Saint James, to disabuse Christians of that false idea which makes us reject the example of the saints as disproportioned to our state. "They were saints," say we, "they are not like us." What then actually happened? Saint Athanasius was a man called Athanasius, accused of many crimes, condemned by such and such a council for such and such a c

Whatever different means
they employ, they all tend to this end. The cause of some going to war, and of others avoiding it, is the same desire in both, attended with different views. The will never takes the least step but to this object. This is the motive of every action of every man, even of those who hang themselves.

And yet, after such a great number of years, no one without faith has reached the point to which all continually look. All complain, princes and subjects, noblemen and commoners, old and young, strong and weak, learned and ignorant, healthy and sick, of all countries, all times, all ages, and all conditions.

A trial so long, so continuous, and so uniform, should certainly convince us of our inability to reach the good by our own efforts. But example teaches us little. No resemblance is ever so perfect that there is not some slight difference; and hence we expect that our hope will not be deceived on this occasion as before. And thus, while the present never satisfies us, experience dupes us and, from misfortune to misfortune, leads us to death, their eternal crown.

What is it, then, that this desire and this inability proclaim to us, but that there was once in man a true happiness of which there now remain to him only the mark and empty trace, which he in vain tries to fill from all his surroundings, seeking from things absent the help he does not obtain in things present? But these are all inadequate, because the infinite abyss can only be filled by an infinite and immutable object, that is to say, only by God Himself. He only is our true good, and since we have forsaken him, it is a strange thing that there is nothing in nature which has not been serviceable in taking His place; the stars, the heavens, earth, the elements, plants, cabbages, leeks, animals, insects, calves, serpents, fever, pestilence, war, famine, vices, adultery, incest. And since man has lost the true good, ev

Shall it be
on justice? Man is ignorant of it.

Certainly, had he known it, he would not have established this maxim, the most general of all that obtain among men, that each should follow the custom of his own country. The glory of true equity would have brought all nations under subjection, and legislators would not have taken as their model the fancies and caprice of Persians and Germans instead of this unchanging justice. We would have seen it set up in all the States on earth and in all times; whereas we see neither justice nor injustice which does not change its nature with change in climate. Three degrees of latitude reverse all jurisprudence; a meridian decides the truth. Fundamental laws change after a few years of possession; right has its epochs; the entry of Saturn into the Lion marks to us the origin of such and such a crime. A strange justice that is bounded by a river! Truth on this side of the Pyrenees, error on the other side.

Men admit that justice does not consist in these customs, but that it resides in natural law

We have
about six hundred and twenty communicants, which include almost all our adult persons. The church was very large before; but persons never thronged into it as they did in the late extraordinary time.-Our sacraments are eight weeks asunder, and I received into our communion about a hundred before one sacrament, fourscore of them at one time, whose appearance, when they presented themselves together to make an open explicit profession of Christianity, was very affecting to the congregation. I took in near sixty before the next sacrament day: and I have very sufficient evidence of the conversion of their souls, through divine grace, though it is not the custom here, as it is in many other churches in this country, to make a credible relation of their inward experiences the ground of admission to the Lord's supper.

I am far from pretending to be able to determine how many have lately been the subjects of such mercy; but if I may be allowed to declare any thing that appears to me probable in a thing of thin nature, I hope that more than 300 souls were savingly brought home to Christ, in this town, in the space of half a year, and about the same number of males as females. By what I have heard Mr. Stoddard say, this was far from what has been usual in years past; for he observed that in his time, many more women were converted than men. Those of our you

One cannot have one's source power and eat it too.
If the reflected energy is part of the forward energy,
it cannot also flow into the source.

> The equations you present above hold just as well
> when there is no reflection at the source.

How can there be no reflection at the source when
the source is dissipating zero power?

> If you don't think any understanding can be gained
> from examples with ideal components, please read
> no further.

If those ideal components are far removed from being
realizable in the real-world, you have yourself a deal.
Until you can provide an example of a real-world source
approaching a zero real-world impedance, there is no
reason to read any further. You might as well just say,
"God causes everything." and be done with it.

Hi Cecil

Non locality is another description of the phenomenon, or 'spooky action at a distance' is another term that has been used. The instantaneous interaction of entangled particles, no matter what the distance, follows as a mathematical consequence of quantum theory.

These actions have been observed in laboratories but to date no one has come up with an entirely satisfactory explanation for what is going on. Similar weird observations in particle accelerators show particle tracks disappearing and reappearing at some distance away. Richard Feynman touched upon the possibilities of these events happening when he came up with Feynman diagrams to describe the interaction of particles with photons. Certainly at sub atomic scales, time appears to be somewhat elastic and reversible under particular conditions.

I personally feel (with very little justification) that wave particle duality breaks down if velocities exceed the speed of light and in the absence of one or the other, an object effectively disappears from our perception (and perhaps in effect from our universe).

Sorry to interrupt the WAVE-PARTICLE Duality seminar but...

Any comments on the SpiderBeam antenna?

It's a sort of maxed-out Moxon such that the director and reflector
elements are bent toward the center of the antenna.

Apparently it is frequently used on DXpeditions.

There is a version for home use...a kit and the elements are wires.

Anyone using one or care to comment?

(My understanding is that it can send and receive both waves and particles.)

I believe that attempting to use FTL particles to explain certain phenomena, or more likely, using certain phenomena to theorize FTL paricle travel, is generally a practice reserved for non-physicists, science fiction writers and the like. Almost any true, practicing physicist will tell you that they and their colleagues don't believe in that stuff. Sorry, the universe may be interesting but it isn't THAT interesting. Too bad. The whole concept falls apart when causality comes into play. It is not even a paradox; it is worse than that. If I initiate an event to cause tachyons (or whatever you choose to call these FTL particles) to exist, then the particles must have existed (and must be observed) before that causation event which produced them was initiated. So what if you fully intend to cause the event and then change your mind at the last moment and decide not to cause it. How does your FTL particle know that you will not push the button so it knows to refrain from existing? So, although there is room in the special relativity theory for particles than can go no slower than light (the other side of the hyperbola), causation prohibits them from existing in the real world. If you were to believe in some supreme controlling authoritiy who could predict whenever you would push the button and make the particle appear, then it could be true. I am a bit too agnostic for that, however...it would be the only expalantion for the effect occuring prior to causation . This is reminiscent of the faith-based science that certain English majors use here when saying "just believe me, it's true; RF and acoustic waves interact. Why, it's a matter of public knowledge!".

Probably because a lot of folks don't realize that the power isn't
divided equally among elements in most ham phased arrays. A lot of the
textbook examples are for microwave applications (e.g. radar) where they
do assume equal powers to each element, but that's where the array is
specifically designed to present 50 ohm resistive feedpoint impedances
at all ports, regardless of phasing, especially if it's an active array
with amplifiers at each T/R module.

There's also plenty of examples out there for microwave broadside arrays
of many identical elements at uniform spacing >1/2 wavelength, for which
a equal power divider actually works fairly well. (or, at least, it's
easy to analyze)

Hecht is quite correct. This is a standard technique in several areas of physics research. I personally spent several years in my relative youth designing, building, and using photon counting apparatus.

Sadly true!

The problem with FTL is that causality is a big issue. Some would have us believe that the universe splits into two at every such event so that both alternatives exist. That really does make the mind boggle.

My only suggestion to the causality problem is that time does not necessarily progress in the same manner at quantum scales as it appears to do for macro objects. It having been proven that the space time continuum is warped by gravitation, with even the earth having a measurable effect, it seems logical that time reversal or suspension at quantum scales would not be beyond probability.

We just do not have the tools at present to prove any hypothesis, hence all the theories... :-)

Cheers

>I didn't see any UHF diodes on that site, did anybody else?

Click on "RFICs/Discretes" on the left. On the resulting page,
look in the "Product Tree" in the center, and click on "Schottky
Diodes".

The 5082-2800 series (glass-beaded) are specifically cited in their
data sheet as "particularly well suited for the UHF mixing needs of
the CATV marketplace".

In surface-mount, the HMPS-282x series are described as "RF/Microwave
mixer/detector diode", while the HSMS-282x "has been optimized for use
in RF applications, such as DC biased small signal detectors to 1.5
GHz, biased or unbiased large signal detectors to 4 GHz, mixers and
frequency multipliers to 6 GHz" according to the series data sheet.

I think that covers UHF pretty well, even if the web page and data
sheets don't use the specific term "UHF".

Non-sequitor. If the impedance is not well-defined,
then it is impossible to draw any conclusions about
reflections at the generator. So any claim of total
reflection in such an environment would be invalid.

In the example, the source is not dissipating zero
power. You should consider examining the example.

Feynman talks a lot about when the waves get weaker,
the clicks from the detectors get farther apart, but
the intensity of each click doesn't get any weaker.

Hi Gene,

I cannot ascribe its construction to my youth (having built it only 4
or 5 years ago), but I've got one sitting at my elbow that I use as a
random number (AKA white noise) generator. I'm using a Burle (nee
RCA) 931A, which isn't optimal, but still pumps out a flat spectrum to
at least 30MHz. It certainly works fine into my Audio Card.

There was an 'if' clause. YOU made the choice to avoid
the opportunity for learning.

I notice that your own examples are often constructed
with ideal components, so this aversion to ideal
components is not universal. Perhaps only when it
can be conveniently used to avoid situations where
your deeply held beliefs may be threatened?

Keith, this special case is covered in my Worldradio
energy analysis article at:

http://www.w5dxp.com/energy.htm

I agree with your special case analysis. The reason that
it is a special case is that at the generator terminals:

(Vf)^2 + (Vr)^2 = (Vf+Vr)^2

i.e. you have chosen the one special case where the
superposition of powers yields a valid result.

Quoting my article with some special characters replaced by
ASCII characters:

"If A = 90 deg, then cos(A) = 0, and there is no
destructive/constructive interference between V1 and V2. There
is also no destructive/constructive interference between V3 and
V4. Any potential destructive/constructive interference between
any two voltages is eliminated because A = 90 deg, i.e. the

voltages are superposed orthogonal to each other (almost as if they were not coherent)."

At the generator terminals, you have chosen the one phase angle between Vf and Vr that will result in zero interference. Whether by accident or on purpose is unclear. The phase angle between Vf and Vr at the generator terminals is 90 degrees resulting in zero interference. Your analysis is completely correct for this special case. Now try it for any length of feedline between 0 deg and 180 deg besides 45 deg and 135 deg. 90 degrees would be very easy to calculate.

It was an obvious joke, Keith. I just analyzed your
analysis and pointed out that your choice was a special
case that made it OK to superpose powers. Shame on you.

>
> So all the energy is accounted for, as expected.

I'm surprised you don't see your own contradiction.

If, as you say, the reflected wave is not reflected by
the source, then the reflected wave flows through the
source resistor to ground and is dissipated.

If the reflected wave is dissipated in the source
resistor, it cannot join the forward wave.

The forward wave is 25 joules/sec. The source is
supplying 18.75 joules/sec. If the reflected wave
is dissipated in the source, where is the other
6.25 joules/sec coming from? Is it mere coincidence
that the reflected wave is 6.25 joules/sec????

Hint: You cannot eat your reflected wave and have it too.

If the forward power is greater than the source power,
the reflected wave is joining the forward wave, i.e.
being reflected by the source.

Here is an example of the reflected wave flowing through
the circulator resistor and being dissipated.

Source---1---2----45 deg 50 ohm feedline---150 ohm load
\ /
|
50 ohms

But in this example Psource = Pforward in order to satisfy
the conservation of energy principle which your example
does not.

> Vg(t) = 55.902 cos(wt - 26.565d)

Whoa! You started with 50 volts applied to the forward line, then froze the wave by finding the time phase of the wave. Mathematically, you want to find the voltage at the generator which is the sum of the terms Vf.g and Vr.g. The sum of those terms is 50 + 0 = 50, not 55.902 /_ -26.565d.

The same error here.
Ig = 1 /_ 0d - 0.5 /_ -90d
= 1 - 0
= 1

No. Based on the way I read your CORRECTED sums, the power at the generator Pg should be 50 * 1 = 50.

With the circuit and conditions presented, the reflected voltage and current return out of phase in time with the source voltage and current. A standing wave condition of 3:1 would always exist throughout the system.

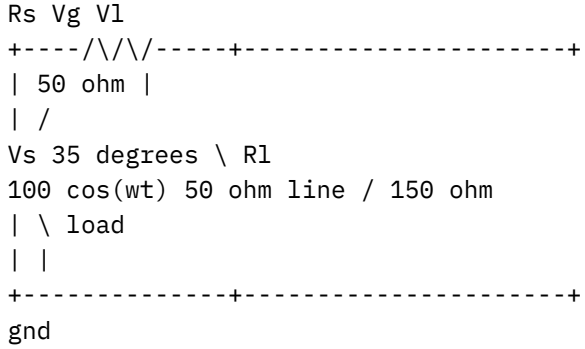
I choose 45 degrees because it was not 90, the standard value
used which leaves all sorts of misleading artifacts when doing
analysis. I noticed that a few artifacts also exist at 45 but
I had hoped they would not mislead. I see I was wrong.

Below, I have redone the analysis with a 35 degree line.

The analysis is based on no reflection occurring at the
generator, and the energy flows still balance as expected.

The analysis for a 35 degree line follow.

This simple example has a voltage source in series
with a 50 ohm resistor, driving 35 degrees of 50
ohm line connected to a 150 ohm load.



The voltage source in series with the 50 ohm
resistor forms a generator.

Vs(t) = 100 cos(wt)

or, in phasor notation

Vs = 100 /_ 0d

where d is degrees or 2*pi/360 when converting to radians
is appropriate.

When the source is turned on, a wave travels down the
line. At the generator terminal (Vg), the forward voltage
is:
Vf.g(t) = 50 cos(wt)
Vf.g = 50 /_ 0d
since the voltage divided evenly between the source
50 ohm resistor and 50 ohm impedance of the line.

At the load, the voltage reflection coefficient is

RCvl = (150-50)/(150+50)
= 0.5

The forward voltage at the load is

Vf.l(t) = 50 cos(wt - 35d)
Vf.l = 50 /_ 35d

The reflected voltage at the load is

Vr.l(t) = 0.5 * 50 cos(wt - 35d)
= 25 cos(wt - 35d)
Vr.l = 25 /_ -35d

The voltage at the load is

Vl = Vf.l + Vr.l
= 50 /_ -35d + 25 /_ -35d
= 75 /_ -35d
Vl(t) = 75 cos(wt - 35d)

At the generator, the voltage reflection coefficient is

RCvg = (50-50)/(50+50)
= 0

so there is no reflection and the system has settled
after one round trip.

The voltage at the generator is, therefore,

Vg = Vf.g + Vr.g
= 50 /_ 0d + 25 /_ (-35d -35d)
= 50 /_ 0d + 25 /_ -70d
= 63.087640 /_ -21.862219d
Vg(t) = 63.087640 cos(wt - 21.86221d)

Currents can be similar computed...

If.g(t) = 1 cos(wt)
If.g = 1 /_ 0d

RCil = -(150-50)/(150+50)
= -0.5

If.l(t) = 1 cos(wt - 35d)
If.l = 1 /_ -35d

Ir.l(t) = -0.5 * 1 cos(wt - 35d)
= -0.5 cos(wt - 35d)
Ir.l = -0.5 /_ -35d

Il = If.l + Ir.l
= 1 /_ -35d - 0.5 /_ -35d
= 0.5 /_ -35d
Il(t) = 0.5 cos(wt - 35d)

And just to check, from V = I*R
R = V / I
= Vl(t) / Il(t)
= (75 cos(wt-35d)) / (0.5 cos(wt-35d))
= 150
as expected.

RCig = -(50-50)/(50+50)
= 0

Ig = If.g + Ir.g
= 1 /_ 0d - 0.5 /_ (-35d -35d)
= 1 /_ 0d - 0.5 /_ -70d
= 0.952880 /_ 29.543247d
Ig(t) = 0.952880 cos(wt + 29.54324d)

Now let us see if all the energy flows balance properly.

The power applied to the load resistor is

Pl(t) = Vl(t) * Il(t)
= 75 cos(wt - 35d) * 0.5 cos(wt - 35d)

Recalling the relation
cos(a) * cos(b) = 0.5(cos(a+b)+cos(a-b))

Pl(t) = 75 * 0.5 * 0.5 (cos(2wt-70d)+cos(0))
= 18.75 cos(2wt-70d) + 18.75 cos(0)
= 18.75 cos(2wt-70d) + 18.75

Since the average of cos is 0, the average power is

Pl.avg = 18.75

To confirm, let us compute using

Pavg = Vrms * Irms * cos(theta)

Pl.avg = (75 * 0.707) * (0.5 * 0.707) * cos(-35d-(-35d))
= 18.75 * 1
= 18.75

Agreement.

Now at the generator end

Pg(t) = Vg(t) * Ig(t)
= 63.087640 cos(wt - 21.862212d) * 0.952880 cos(wt + 29.543247d)
= 63.087640 * 0.952880 * 0.5 (cos(2wt+7.681035)+cos(-51.405466))
= 30.057475 cos(2wt) + 30.057475 * 0.623805
= 30.057475 cos(2wt) + 18.750004
Pg.avg = 18.75

Good news, the average power into the line is equal to
the average power delivered to the load, as required to
achieve conservation of energy.

Now let us check Pf and Pr

Pf.avg = Vfrms^2 / Zo
= (50*.707)^2 / 50
= 25

Pr.avg = Vrrms^2 / Zo
= (25*.707)^2 / 50
= 6.25

Pnet.avg = Pf.avg - Pr.avg
= 25 - 6.25
= 18.75

Again, as expected, the average energy flow in the line
is equal to the average power into the line and the average
power out of the line.

So, contrary to Cecil's assertion, an analysis based on
'no reflections at the source', has not resulted in any
violation of conservation of energy. This is good.

It is instructive to continue the cross-checking.
Let us validate the input impedance of the line.

Using a Smith chart
(http://education.tm.agilent.com/index.cgi?CONTENT_ID=5),
and going towards the source from a 150 ohm load on a 50 ohm
line yields

Zin.smith = 41.28 - j51.73
= 66.18 /_ -51.41

Dividing the voltage by the current at the input to the
line...

Zin = Vg / Ig
= 63.087640 /_ -21.862219d / 0.952880 /_ 29.543247d
= 66.207329 /_ -51.405466
= 41.300466 -j51.746324

yields the same result as the Smith chart.

Lastly let's compute the power provided by the source...

Ps(t) = Vs(t) * Is(t)
= 100 cos(wt) * 0.952880 cos(wt+29.543247d)
= 95.288000 * 0.5 (cos(2wt+29.543247d) + cos(-29.543247d))
= 47.644000 cos(2wt + 29.543247) + 47.644000 * 0.869984
= 47.644000 cos(2wt + 29.543247) + 41.449507

Ps.avg = 41.449507

and that dissipated in the source resistor

Prs(t) = Vrs(t) * Irs(t)
= (Vs(t)-Vg(t)) * Ig(t)
= (100 cos(wt) - 63.087640 cos(wt - 21.862219d)) * 0.95288
cos(wt + 29.543247d)
= 47.643989 cos(wt + 29.543247d) * 0.952880 cos(wt +
29.543247d)
= 47.643989 * 0.952880 * 0.5 (cos(2wt + 59.086480d) + cos(0))
= 22.699502 cos(2wt + 59.086480d) + 22.699502

Prs.avg = 22.699502

The power provided by the source is equal
to the power dissipated in the source resistor and the
power dissipated in the load resistor.

41.44950 = 22.699502 + 18.75

So all the energy is accounted for, as expected.

When the source impedance is the same as the line
impedance, there are no reflections at the source
and all the energy is properly accounted. There is
no violation of the conservation of energy principle.

...Keith

PS. It is worthwhile to note that there are a large
number (infinite) of source voltage and source
resistor combinations that will produce exactly
the same final conditions on the line. But if
the source resistor is not 50 ohms, then there
will be reflections at the source and it will
take infinite time for the line to settle to
its final state.

Vr.g is the reflection of Vf from the load so it is
a delayed version of Vr.l, the delay being another
45 degrees.

The reflected voltage at the load is
25 /_ -45d

Another 45 degrees makes it
25 /_ -90d
by the time it gets back to the generator terminal.

So the total voltage at the generator is
Vg = Vf.g + Vr.g
= 50 /_ 0d + 25 /_ (-45d -45d)
= 50 /_ 0d + 25 /_ -90d
= 55.902 /_ -26.565d
Vg(t) = 55.902 cos(wt - 26.565d)

[snip]

Similarly for Ig and Ig(t) and Pg.avg and Pg(t).

[snip]

> With the circuit and conditions presented, the reflected voltage and current return out of phase in time with the source voltage and current. A standing wave condition of 3:1 would always exist throughout the system.

Agreed, though it might be slightly more correct to say
that there is a 3:1 VSWR on the transmission line.

Keith Dysart wrote:
> So, contrary to Cecil's assertion, an analysis based on
> 'no reflections at the source', has not resulted in any
> violation of conservation of energy. This is good.

Again your analysis violates the conservation of energy
principle. The only way to balance your energy equation
is for your source to supply 25 joules/sec.

IF THE REFLECTED WAVE IS NOT REFLECTED FROM THE SOURCE,
IT FLOWS THROUGH THE SOURCE RESISTOR AND IS DISSIPATED
IN THE SOURCE RESISTOR. THAT REFLECTED WAVE ENERGY IS
THEREFORE NOT AVAILABLE TO THE FORWARD WAVE.

You cannot eat your reflected wave and have it too.

The standard equation is:

Psource = Pfor - Pref = Pload

But you have taken away the reflected energy and
dissipated it in the source resistor. So your new
equation becomes:

Psource = Pfor + ????????
18.75w = 25w + ________

You say the source power is 18.75 joules/sec and the
forward power is 25 joules/sec. If none of the reflected
energy is available to the forward wave, where did the
extra 6.25 joules/sec come from? Is it sheer coincidence
that the reflected wave is associated with 6.25 joules/sec
that are now missing from the above equation?

Here is an example of the reflected wave flowing through
a circulator resistor and being dissipated.

Source---1---2----45 deg 50 ohm feedline---150 ohm load
25w \ / 18.75w
|
50 ohms
6.25w

But in this example Psource = Pfor in order to satisfy
the conservation of energy principle which your example
does not.

> being reflected by the source.

I wondered if this bit of numerology would lead to
confusion, and apparently it has.

Consider what happens when the source is first turned on.
Immediately
Pf.avg = 25 W

Sometime later the forward wave reaches the load and a
reflected wave is returned
Pr.avg = 6.25 W

Later, this wave arrives back at the generator.

How does this reflected wave of 6.25 W affect the already
present forward wave of 25 W when it arrives back at the

generator. It affects it not one iota. The forward power
remains the same, the forward voltage remains the same
and the forward current remains the same. This is the
meaning of no reflection.

The one thing that changes is the net average power which
decreases to 18.75 W.

I would suggest that you start with the circuit I proposed
and analyze it with the technique of your choice.
What is the final Vf, Vr, Pf.avg, Pr.avg, Pg.avg and Pl.avg?
Are your answers different than mine?
If so, we can explore which approach is in error.
What happens at the generator when the first reflection
arrives back at the generator?
Does Vf and Pf.avg change? Or remain the same?

When Pf.avg remains the same, how can it be claimed that
the reflected wave is re-reflected?

...Keith

OK, 55.902 /_ -26.565d is another way of expressing 50. I should have realized that identity. Sorry to have troubled you.

Google is your friend.

NXP (http://www.nxp.com/) is sold by Digikey (see, e.g., page 1152 of the catalog). You might have better luck searching by the name Philips to find part numbers.

http://www.avagotech.com/ for diodes from Avago (they have things like the 1N5711) more to the point, lots of Ap notes.. see, for instance, number 986 (Avago was part of HP, but actually was originally Avantek... on the other hand, HP always made diodes, so maybe Avago is some of Avantek (MMIC) and some of HP (diodes))

http://www.vishay.com/ for Vishay. Look for small signal diodes

One should also look at Microwaves 101
http://www.microwaves101.com/encyclopedia/detectors.cfm

and they have a "where are they now" page on their website, to help track down who sells brand X now.
http://www.microwaves101.com/encyclopedia/wherenow.cfm

I don't think you'll find a website that compares diodes for RF
performance.

A couple reasons spring to mind:
1) Most RF designers have their favorite parts that they've used before,
so they will tend to just use them again. If their favorite part
doesn't work, then they'll start hunting through the pile of datasheets
and books or ask around for suggestions (e.g. just like on this list)

2) The performance is highly application specific. You can look at the
basic numbers (PIV, forward resistance, capacitance, etc.) to get an
idea, but it's really going to come down to how it works in YOUR
circuit, and that's usually a breadboarding or modeling exercise (most
parts have pretty good SPICE or other models available). Just because
manufacturer X's 1n5711 works great in my mixer doesn't mean it will
work great in your frequency tripler or someone else's RF switch.

3) There are significant differences in performance between
manufacturers for the same JEDEC partnumber (e.g. 1n5711). In a lot of
high performance applications, you actually depend on some non-datasheet
performance property. For instance, there's a small company in England
that makes a low noise JFET that is unique in the world and prized by
folks building charge/voltage converters, even though it's got a

standard 2N number. And then, they still get a batch of them and hand select.

4) Parts selection is something of competitive value. Someone who designs RF stuff for a living (i.e. someone who would be likely to know all the trade offs between various part types and mfrs and could generate a comparative website) is going to be encouraged by their employer to not publish this for the whole wide world.

Hello,

Does anyone know if there's a way to determine the velocity factor of various metal tube types, diameters and gauges?

Also, on the same subject... Is there any reason why a collinear couldn't be constructed from metal tubing pieces, in the same basic method of a coax collinear?

Thanks for any help,

Dave

I'm not sure just what you mean by "the velocity factor" of metal tubes. Generally it's not the metal but the dielectric that determines velocity factor.

But for sure you can construct a collinear from metal tubing pieces. After all, coax is just a metal tube (which may be braided, foil or solid) surrounding a center conductor.

Cheers,
Tom

Maybe a more drastic example will help.

```
Rs Vg Vl
+----/\/\/-----+----------------------+
| 50 ohm |
| /
Vs 90 degrees \ Rl
100 cos(wt) 50 ohm line / 1 ohm
| \ load
| |
+--------------+----------------------+
gnd
```

Current through the source: Is = 0.0392 cos(wt).
The source is supplying 1.96 watts. That is all the
power available to the entire system.

You say the forward power is 25 watts and that none
of the reflected power is reflected at the source.

How can there be 25 watts of forward power when
the source is supplying only 1.96 watts and none
of the reflected energy is joining the forward
wave?

And of course there's the other side of the coin on number 4: a manufacturer isn't going to provide a comparison with other manufacturers' parts for at least a couple reasons. They want to focus attention on their own parts, and they have no control over any changes another manufacturer may make in their parts and thus no way to insure accuracy of such a comparison.

The tough part of Suzy's quest is finding an acceptable diode in non-surface-mount, it seems to me. I did find that a common 1N4148 non-Schottky performed in my test detector circuit at 450MHz better than I expected, and better than some other diodes I tried like 1N34 and several other germaniums, and an axial-leaded Schottky or two in the high voltage, high capacitance signal diode class that I believe Wim warned against.

I really appreciated Wim's posting on this topic, and also yours, Jim. Thanks.

Cheers,
Tom

Presuming this is for the 70cm reflectometer, I have already pointed
Suzy to two Australian retailers with diodes that should work.

My assumption is that she will design the detector to work above the
square law region, and the usual practice is then to design the coupler
so that the dc voltage is much greater than the diode voltage drop, and
the scale shape is relatively independent of the diode drop.

Another retailer is minikits.com.au. Mark has 1N5711 for 0.66, and it
will probably cost $7 for postage. Last time I tried to buy diodes from
Mark, he wanted to know what I wanted them for, whether it was a worthy
project, and would deem to sell me only a small quantity. I subsequenctly
bought a couple of hundred 1N5711 on Ebay for < $15.

Ebay is a huge source of schottky diodes (if you must prefer schottky).
Just search for schottky, sbd, barrier, hot carrier etc, then get the
specs for each one and see if they are suitable. Thing is that most the
signal ones will be SM packages of one or two diodes, but they can be
used with pigtails attached.

There are 9 listings on Ebay right now for 1N5711.

Owen

> solid) surrounding a center conductor.

I suspect he means what length would be needed for a resonant quarter or half wavelength. That's a function only of the diameter. You can find graphs of a "shortening factor" for dipoles or some such in numerous places such as the _ARRL Antenna Book_. Or you can get that information very quickly and easily with the free EZNEC demo program from http://eznec.com or with any other antenna modeling program.

But in the end, you still have to cut the tube to the electrical performance desired. Measurements only get you into the ball park. But I know that you knew that. <G>

OK thanks... Actually I was reading something that indicated you
should add in a velocity factor for the tube when using it as a
sleeve. I had never heard of that either, so I wasn't sure. They used .
95 I believe.

So I guess you would go coax center conductor to tube section #1,
braid to center of second coax through section #1 to section #2. Coax
from section #1 through section #2 to section #3 and so on?

Hi Dave,

I presume you mean 0.95, which for a metal tube holding an inner
conductor that is air insulated, then that might be operative. Too
much is left unsaid: like frequency/wavelength, size of tube, any
inner conductor (so as to emulate a coax), any coax within the tube
(to further compound the issue), the length of tube.... in other
words, a lot of missing details. Some are suggestive in your use of
the term sleeve, but you don't provide much to help.

>So I guess you would go coax center conductor to tube section #1,
>braid to center of second coax through section #1 to section #2. Coax
>from section #1 through section #2 to section #3 and so on?

So, what is #1, #2, #3, and so on? I get the impression you have a
vivid image of this in front of you, but you are blocking the view and
I can't see it.

I've used a fair number of 1n914 and 1n4148 diodes for detectors over
the years. It all depends on what you want to get out of it.

The 1N2x and 1N34 diodes work well in their special mounts (like as a
waveguide microwave detector), but I think that's a packaging and
connector capacitance issue, mostly.

2025. 7/8th diameter Heliax

Not sure that shouting helps. I do not find any unbalances
with the energy. See below.

> You cannot eat your reflected wave and have it too.
>
> The standard equation is:
>
> Psource = Pfor - Pref = Pload

Yes. Indeed. And just changing to use my terminology...

Pgenerator = Pfor - Pref = Pload

For the example at hand...

Pgenerator = 18.75
Pfor - Pref = 18.75
Pload = 18.75

And the source provides 50 W of which 31.25 is dissipated
in the source resistor and 18.75 is delivered to the
line (Pgenerator, above).

All seems well with world and no energy is left unaccounted.

> But you have taken away the reflected energy and
> dissipated it in the source resistor. So your new
> equation becomes:
>
> Psource = Pfor + ????????
> 18.75w = 25w + ________

As your original equation above

Psource = Pfor - Pref
18.75 = 25 - 6.25

I do not see any issues.

When the source was first turned on, 25 J/s flowed from
the generator into the line.
Pfor = 25 W

After the reflected wave makes it back to the generator,
25 - 6.25 -> 18.75 J/s are flowing in the line.
Pfor - Pref = 18.75 W

And the generator output has also reduced from 25 W to
18.75 W, so all is still in balance.

I am having difficulty determining where you think there
is a violation of the conservation of energy principle.

...Keith

PS Do not be fooled by the numerology where 25 + 6.25
gives 31.25. For the 35 degree line, the corresponding
numbers are
Ps = 41.449507
Prs = 22.699502
Pg = 18.75
Pf = 25
Pr = 6.25
Pl = 18.75

Pg = Pf - Pr = Pl
Ps = Prs + Pg
All as expected. No missing energy.

The answer would be clear to you if you were to
complete the analysis.

Please compute:
Pfor
Pref
Vfor
Vref
at the point Vg, both before and after the
reflected wave makes it back to the point Vg.

When you find (as you will), that Pfor and Vfor
do not change when the reflected wave returns,
it should be difficult to assert that the
reflected wave is re-reflected at Vg.

If the reflected wave was re-reflected at Vg,
there would necessarily be a change to Vfor
and Pfor.

Hi Jerry,

Now that you mention it, it does resemble the #1, #2, #3, and so on -
so described. This is also known as a Franklin Array, but not in the
classic design. Problem here is that the phasing of the radiating

elements' exteriors are critical to the operation of the antenna, insofar as gain goes. On the other hand, the wavelength dimension of the inside of the same elements are critical to the operation of the antenna, insofar as matching goes. That the two electrical wavelengths might match and possibly work is a guess as the author states:
"we chose LMR-400 as it was lying on the floor"

The commercial builders of the same style antenna use simple wire with the occasional spacer.

If you are wanting to make a coaxial collinear using solid metal tube (copper? aluminum?) for the elements, why not just make that tube the outer conductor of coaxial sections. The inner conductor can be a piece of solid copper wire, that then connects to the outer conductors of the adjacent sections. Or maybe that's what you mean; it's not really very clear to me.

Be aware that the phasing of the coaxial collinear is controlled by the electrical length of the coaxial sections. For a "flat pancake" pattern they should be an electrical half wave. Depending on the insulation, that may be considerably shorter than a freespace half wave. That does not directly matter to the antenna; non-resonant antennas work just fine. The feedpoint impedance will be the parallel combination of all the feedpoints (assuming low loss electrical half-wave connecting sections), transformed by any coaxial stub between the last feedpoint and the feedline. The "feedpoints" are all the gaps between sections.

Cheers,
Tom

Wrong product - that's the HexBeam!

Try www.spiderbeam.net

There are eight different models, each covering three or more bands from 30m up to 10m, and starting from $500 for a kit. Instructions are also freely available to build it yourself from local materials.

The Spiderbeam was originally designed as a highly portable multiband yagi. It uses full-length interlaced elements, and the design has been computer optimized for maximum performance within the boundaries of the cross-braced "diamond" shape - 10 metres (33 feet) from corner to corner. That computer design has then been translated with unusual care into detailed practical assembly instructions.

Be aware that the Spiderbeam was originally developed as a lightweight beam for portable operation on a push-up mast. For these applications it really shines - many DXpeditions out of Europe have used Spiderbeams with great success. With practice it can even be erected single-handed.

But the cord-and-wire braced construction is not suitable for every home-station site (Spiderbeams and trees make a very bad combination) and even the heavy-duty version may not be suitable for year-round survival in every kind of climate. Also, the Spiderbeam needs to be fully assembled on the ground - with is fine for the original concept of a push-up mast, but it can cause installation problems for tower owners.

What you'll see on the *correct* Spiderbeam review page at eham.net (http://www.eham.net/reviews/detail/3688)
is the expected mixture of "5/5" reviews from people whose locations are Spiderbeam-friendly... and lower ratings from people whose locations are not.

[For the record, my own relationship with Spiderbeam is that I bought one for use at a new home, but ran into zoning/planning problems about cutting back the trees. Reluctantly I sold the beam to a DXpedition group, where I'm sure it will do very well.]

> When you find (as you will), that Pfor and Vfor
> do not change when the reflected wave returns,
> it should be difficult to assert that the
> reflected wave is re-reflected at Vg.

Not difficult at all. I've added the powers to the
diagram above. The reflected power is ~23 watts.
The power dissipated in the source resistor is
~0.04 watts. The reflected power is obviously *NOT*
being dissipated in the source resistor so where
is it going instead? The answer is destructive
interference at the source resistor is redistributing
the reflected energy back toward the load as an
equal magnitude of constructive interference.
I call that a reflection. The redistribution of
energy due to interference is a well known and
well understood phenomenon in optical physics but has
been virtually ignored in the field of RF engineering.

It is not a conventional reflection. It is wave
cancellation in action. It is obeying the following
equation:

Ptot = P1 + P2 - 2*SQRT(P1*P2) where
-2*SQRT(P1*P2) is the destructive interference term.

> If the reflected wave was re-reflected at Vg,
> there would necessarily be a change to Vfor
> and Pfor.

Nope, not true. The phase angle
between the voltages determines which direction the

energy flows. If the above example is changed to
1/2WL instead of 1/4WL, the forward and reflected
voltages and powers remain the same but the interference
at the source resistor changes from destructive to
constructive and the source resistor heats up.

Sorry, I didn't give many details. My idea was basically for a commercial band antenna that needs to cover a fairly wide range in the 5xx-4xx bands. I've had good performance using fairly large tubing for wide bandwidth requirements on single element designs in the past, but I've never attempted a multi element design using the same materials. Lets say I'd be using 1 1/2" .065 aluminum tube. Testing would be required to find the ideal length. Yes, I'm basically trying to see if something along the lines of the web page plans posted above could be utilized with a larger size tube. I just wasn't sure about how it could be wired up. But looking at those plans, I think I see the way it could be done. It would just take a lot of experimenting to get the dimensions right.

I saw this post this afternoon and tried it at the office. Works great, I can get into the free wifi from the airport. I just taped a piece of aluminum foil to the wall in a corner and set my USB wifi transceiver in front of it. Took about 5 minutes to rig up. Unfortunately I can only use it in the evenings as there is too much ground traffic between my location and the WIFI source the rest of the day.

Oh bother . . Yes, I blew it Ian. TNX.

I fail to understand why anybody who knows what's up would buy a
Spiderbeam when a light-duty cubical quad would have a considerably
smaller footprint and marginally better performance. Beyond the fact
that nobody I know about is selling light-duty "expedition quality"
quads off the shelf.

I really like the coaxial collinear design for relatively narrowband work. The coaxial connecting stubs (whose outside surfaces are also the radiating elements) keep the phasing locked down tightly. Unfortunately for your application, that very advantage for narrowband designs is a killer for broadband. That is, the pattern will change from a "flat pancake" at the nominal design center frequency to a cone up or down, above or below the design center frequency.

You can mitigate that to some extent by feeding the coaxial collinear antenna in the center (with the feedline balanced and perpendicular to the antenna axis for some distance) instead of at an end; in that case, you can think of the pattern as a cone going one way for the section above the feedpoint, and by symmetry, a cone going the opposite direction for the section below, and the sum of the two results in just a lowering of the gain--not so flat a pancake--when operating off the design center frequency.

But a better way to do a broadband vertical collinear is to feed several dipoles, stacked end-to-end (with some gap from one to the next), each fed with the same electrical length of feedline, with the far ends of all the feedlines paralleled. If the gap from one dipole to the next is enough that the mutual impedances among the dipoles are all small, then each dipole will have current very nearly in phase with the others and the radiation pattern will be perpendicular to the axis of the dipoles. It's a messier feed arrangement, but it's much better for keeping the antenna currents in phase along the whole antenna across a relatively wide frequency range.

Cheers,
Tom

Hi Dave

It reads as thouigh you want to increase the signal strength at the
horizon by building a colinear omniazimuth array of dipoles. That is not a
simple thing to do when the gain is high and the bandwidth is 25% of the
center frequency.
It is fairly simple to model the pattern any configuration you are
considering. If you are at all interested in developing capabbility in
antenna building, you can get alot of information with EZNEC.
There are lots of guys lurking in this group who can and will help you.

You can avoid the problem of different feedpoint impedances due to mutual coupling by using lines of an odd number of quarter wavelengths to feed the elements. If you use lines of those lengths all going back to a common point, the currents in the elements will forced to be equal in amplitude and phase regardless of differences in their feedpoint impedances. There's more about this in Chapter 8 of the _ARRL Antenna Book_. It's become known as the "current forcing" method.

Has anybody had any experience using a helical antenna for
transmissions. I put a small helical antenna (65' 14# wire, 172 turns
on 1-3/8" dowel) on my antenna tuner: on 40 meters (7MHz) the SWR was
about 8:1; on 15 meters (21MHz) the SWR was 1.6:1). I thought the 40M
would tune better than the 15M because 65' is about 40M's 1/2 wl.

My antenna tuner manual suggested a balun to tune in any band that
doesn't initially tune-up. I'm thinking the ubiquitous 4:1 balun.

Suggestions, comments?

Tnx,

Yes, I thought about mentioning this, except that in this case it won't (or at least may not) work very well. I like to think that a practical antenna of this sort is nicely built with nominally one wave long doublets; it saves on feedpoints. Then, assuming the the feedlines go perpendicular at least 1/4 wave away from the feedpoints, that means the feedlines are at least 3/4 wave long, for just a two-dipole antenna. Taking into account the fact that the velocity factor in the line is likely going to be noticably less than 1, it's probably 5/4 wave minimum we're faced with, and more if there are going to be more elements than four half-waves. But if Dave99 wants to cover 100MHz centered around 500MHz, or maybe even more, as I got from one of his postings in this thread, and we make the lines 5/4 wave long on 500MHz, then 10% removed in frequency from that, they'll be 5/40 or 1/8 of a wave off from 5/4. If the lines were 11/4 wave long, a 10% change in frequency would result in more than a quarter wave change in electrical line length. At least this is an issue to be aware of. In general, lines that are long in terms of number of wavelengths change length by electrical quarter waves rather rapidly with changes in frequency, and it's easy to forget about that till it bites you and leaves a scar for you to remember.

But after all that, I don't think the mutual impedance thing is all that much of a problem for vertically stacked antennas, if you provide even a little space between them. My recollection from modeling this sort of antenna (and fairly careful modeling of the coaxial collinear) is that it's not much of an issue in a practical antenna. "YMMV," but it's easy enough to model in Roy's kindly provided free version of EZNEC, so long as you don't have to go to too many elements, and then I think the licensed-for-a-fee version with way more capability than you'll need for this is still a pretty economical solution for the time it saves.

Cheers,
Tom

Thanks for the kind words about EZNEC. I agree that the problems, if any, can be identified and probably overcome by modeling, whether with EZNEC or some other program. I honestly haven't done it for a group of collinear dipoles, so don't know how much feedpoint impedance alteration takes place due to coupling in that sort of array. I'll certainly defer to your recollection. In any case, if the effect is significant at all, it would only affect the top and bottom elements to any degree, and very possibly not enough to have much of an impact on the overall pattern. You're absolutely right about the potentially severe bandwidth reduction due to using long feedlines. EZNEC and other programs allow you to

include the feedlines in the model, so you can see exactly what the impact would be on both the pattern and feedpoint impedance, for whatever lengths you choose.

> Tnx,

Only a couple of comments.

1. Winding a half wavelength of wire doesn't make an antenna which acts like a half wavelength antenna. Turn-to-turn coupling makes the total wire length a lot less important than other factors like turn diameter and spacing.
2. My experience with using helical antennas is very limited, so other folks can much better tell you what combinations might provide you with a good match. But a helical antenna that's physically quite a bit shorter than a half wavelength will have a low radiation resistance. So if you get a good match without a tuner, it means that there's enough loss to raise the feedpoint resistance to 50 ohms. Another good indication of loss is the bandwidth. If it has low loss, the bandwidth will be very narrow; a wide bandwidth means more loss. Most people, though, run at least several times the power needed to communicate, so trading some efficiency for bandwidth, easy matching, and compact size might be a worthwhile exchange in a lot of cases.

If the loss is low, the feedpoint resistance at resonance would be considerably less than 50 ohms, so a 4:1 balun, with the high impedance side toward the tuner, might make things easier for the tuner.

I got a little taste of what its like to do that a few years ago when I was
able to hook my rig up to an old of the air AM broadcast antenna.
Unfortuately I was not licensed at the time for 160M and could only listen.
Now the antenna is gone.

A helical antenna section can be treated as a piece
of transmission line with a velocity factor and a
characteristic impedance. Knowing the velocity factor
allows one to calculate the approximate length of
the section. On my web page, I have an EXCEL file
that will estimate the VF and Z0 of a helical
antenna: http://www.w5dxp.com/coilZ0VF.xls

To see how this might work, let's assume a 1/2WL
helical dipole for 40m using a helical of 2 inches
diameter and 2 turns per inch on 7.2 MHz. If the
value at A7 on the spreadsheet is less than one,
the VF and Z0 will be in the correct ballpark
- probably within 15%.

For such a coil, the VF is calculated to be 0.207.
1/2WL at 7.2 MHz is 68.3 feet. So how long should
the coil be to be 1/2WL long?

68.3 feet times 0.207 = ~14 feet

Of course, this is not an exact length and must
have turns subtracted (or added) to bring it to
resonance on 7.2 MHz. Since end effects are not
included, the dipole will probably resonate on
a frequency lower than 7.2 MHz. Removing turns
will then bring it to resonance.

Use half of the above for a 1/4WL vertical
section approximately 7 feet high.

Is this the total applied power or the remaining power (Prem)(which is
really the reflected power), where
```

Prem = Z0(If - Ir)^2
= Z0((If^2) +(Ir^2) - 2(If*Ir))

I think these (yours and mine) are both the same equation except that I changed the terms so that we could use it on a transmission line. Z0 is transmission line impedance, If is forward current, Ir is reflected current

Just to clarify,
2*SQRT(P1*P2)
= 2*SQRT((Z*I1^2)*(Z*I2^2)
= 2*Z(I1*I2)

The equation should apply at all locations on the transmission line.

Thanks Roy and Cecil. I'll work on this using your
comments/suggestions.

I'm in a vy antenna unfriendly area: an apartment in the air shaft of
the bldg. So I'm abt 40' from free-air on all four sides. Fortunately,
I'm on the top floor, so I'm trying to get a "stealth" antenna to place

on the roof: something that would be easy to set up/take down. The helical fit that description. But, I'm running QRP (abt 5W) and, taking into consideration what Roy said abt power & efficiency, I'm probably not getting anything out.

One good thing abt this antenna is, for it's size, it does receive better than the random-length wire (abt a 50' rectangle) I had been using inside my apartment. It does have good bandwith - but, as Roy stated this indicates low radiation resistance.

Cecil, I'll work w/ your s/s and play around some more w/ the helical (just for the fun of it, ya know ;-)).

If this doesn't work out I'll try a linearly loaded dipole that N5ESE has on his website.

Thanks to both for your advice.

Roger Sparks wrote:
> The equation should apply at all locations on the transmission line.

What you say is true but there is a caveat. Remember
that I have previously said that interference can exist
without wave cancellation. As long as Z0 remains constant
up and down a transmission line, there is no forward and
reflected wave interaction. They pass each other like
"ships in the night".

The resistor is a physical object. When the forward and
reflected waves superpose at the *resistor*, there is
an obvious interaction, i.e., a permanent interference.
One only has to observe the power dissipated in the resistor
to ascertain that it is not the same as the forward power
plus the reflected power unless the E-fields of the two
waves are 90 degrees apart, a condition for which zero
interference exists.

What is interesting is a procedure for determining the
current through Rs using only powers. We have to be
pretty accurate with the powers to do that. We know
the forward power is 25w. The power reflection coefficient
at the load is [(50-1)/(50+1)]^2 = 0.92311. That makes
the reflected power from the load equal to 23.077 watts.
When the forward wave and reflected wave superpose at
the 50 ohm source resistor, they are 180 degrees out of
phase which makes the interference term minus and
therefore destructive.

25w + 23.077w - 2*SQRT(25w*23.077w) = 0.03845w

That's the dissipation in the 50 ohm source resistor.
So the RMS current is SQRT(0.03845w/50ohm)= 0.02773a

Ig(t) = 1.414(0.02773)cos(wt) = 0.039216 cos(wt)

And that is, indeed, the current through the 50 ohm
source resistor, Rs, using only an energy analysis.

All energy, except 0.03845w, is "redistributed", i.e.
reflected back toward the load. This is all explained
in my energy analysis article at:

http://www.w5dxp.com/energy.htm

I disagree. If the current through the 50 ohm source resistor is 0.039216, then the power in the 50 ohm source resistor cannot be 0.03845w. Namely because 0.039216 * 0.039216 * 50 = 0.076895w (eye-squared-are, matey). Either your power is wrong or your current is wrong. My own calculations show that your current is correct. Therefore, your energy analysis appears to be in error.

You will radiate more power if you make the center half
of the antenna straight wire and use the ends of the
antenna for the helical part. If you haven't considered
top hats on the antenna ends, please do so. The following
would be a pretty good antenna, in fixed font with top
hat loading at the ends.

```
| coil coil |

You seem to have forgotten that since 0.039216 is the maximum
value of current you need to divide the 0.076895w by two.

0.076895w/2 = 0.03845 watts

If we used the RMS value of the current, i.e. 0.039216/1.414
equals 0.027734a, then 50(0.027734)^2 = 0.03845 watts and
all is well.

> I call that a reflection.

When we analyze this circuit we find that there is
no voltage re-reflection when the wave gets back
to the generator. This is clear because Vf does not
change, which it would have to do if any of Vr was
re-reflected.

And yet it appears that you are claiming that power
is reflected at the generator. How can power be
reflected if voltage is not?

You may find the Excel spreadsheet on this page
http://keith.dysart.googlepages.com/generator,line,load,reflection
interesting.

It computes the various results for the circuit we have been discussing. Input Vs, Rs, Rl and line length and it will compute the various voltages, currents and powers.

After entering the circuit parameters, click "First". The circuit conditions at the end of the first round trip will be computed. Click "Next" to have any re-reflection included into the forward conditions for the next round trip.

When Rs is 50 ohms (i.e. it matches the line impedance), the circuit conditions settle to their final state immediately, as would be expected when there is no reflection at the generator. Change Rs to a value other than 50 and it takes many clicks of "Next" before the conditions settle. At each click, Vf changes as some of Vr is re-reflected and added to Vf.

"A photon is not a particle."

For those who might seriously wonder why I would make such an outrageous--some may say idiotic or insane--statement... For those that haven't dismissed it as lunacy... Let me first point out that I did NOT say that a photon isn't a quantum. Indeed, I believe that everything physical in our universe is quantized. But I also believe that until you really get to know photons (and electrons and neutrons and various other things we can only sense and never see directly), you are doing yourself a disservice by calling them by names like "particle" or "wave." That is because, by thinking of them in that way, as particles or as waves, you will miss seeing what they really are. On the other hand, if you call a photon a "quantum of electromagnetic energy," then you may wonder just what THAT is, and may get interested enough to study it in the language that describes it more accurately: the language of quantum theory or the language of quantum electrodynamics.

I was asked for references. I would suggest as a starting point Richard P. Feynman's lecture of April 3, 1962, which was an introduction to quantum behavior. I think the whole of the lecture is worthwhile, but especially the following paragraph:

" 'Quantum mechanics' is the description of the behavior of matter in all its details and, in particular, of the happenings on an atomic scale. Things on a very small scale behave like nothing that you have any direct experience about. They do not behave like waves, they do not behave like particles, they do not behave like clouds, or billiard balls, or weights on springs, or like anything that you have ever seen."

In the lecture, he offers an example of an experiment that, he says, you can NOT explain by using either waves or particles, but it's explained completely and accurately through quantum mechanics. So why talk about photons as if they are particles or as if they are waves, when they behave in total like neither? Why not talk about them as if they are quanta of electromagnetic radiation, which I believe they are?

There's more about this in other Feynman lectures; there's lots more about it in the many quantum mechanics texts that are available.

Although the word 'particle' may be used, I believe it's only through something like quantum mechanics that we can hope to get an accurate picture of how these entities (photons, electrons, mesons, pions, etc.) behave.

The question gave me an excuse to refresh my memory about some books on my own bookshelf:
V. Kondratyev, "The Structure of Atoms and Molecules."
M. W. Hanna, "Quantum Mechanics in Chemistry."
H. A. Kramers, "Quantum Mechanics."
H. G. Kuhn, "Atomic Spectra."
R. E. Dodd, "Chemical Spectroscopy."
In the context of this posting, I did not find in these books a disagreement with the thought that a photon is not a particle.

You may notice a slight interest in photons there among those titles, typically photons of shorter wavelength than we generally use on the ham bands. If you're going to accuse me of not knowing anything about them, perhaps you should get to know me a bit better first.

I'm quite sure I don't really completely know a photon, on its own turf. Feynman in that same lecture told us that HE didn't either. But I do know better than to claim it's either a "wave" OR a "particle." There are plenty of times I don't have to deal with or think about its quantized nature to get valid practical answers to questions dealing with electromagnetic radiation, but there's also no need to waste time discussing whether a photon is something or other when it's clear that it's neither.

Cheers,
Tom
(aargh! no! they're coming to take me back to the asylum! HELP! Now I won't be able to check if there are any responses to this posting...)

Yes, it is a quantum that contains mass and energy.

If you want to call it a particle, you can make a measurement that shows it behaves as a particle (photoelectric effect).

If you want to call it a wave, you can make a measurement that shows it behaves as a wave.

It is either or both, depending upon how you measure it. I agree, it is really up for grabs.

Certainly there are many experiments that will prove it is a quanta.

I sometimes wonder if other species exist elsewhere that can experience, through their own sensory receptors, what quanta/quantum phenomenon really and truly are? Think of the advantage they would have, assuming they had at least equal intelligence to the human species.

Isn't that a linearly loaded dipole?

I saw a picture of a similar antenna in some book I was browsing - the illustration didn't show a center wire, just the coils and the top-hats.

Would you keep the wooden dowel form (for the coils), or would you let them be air-coils (how to keep them from separating [tape])? What lengths would you use for the wire/coils? What type feed line would you use: twin lead or coax? Am I asking too many Qs?

Wait a minute... I've seen examples of this type of ant. on other websites. I'll look those up and you won't have to answer these Qs, which have probably been asked many times before.

N5ESE shows a linearly load dipole that is about 12 feet long (6 ft per pole), twin lead fed with 14 inches of zig-zag wire at the ends. He reports that he had pretty good results w/ this ant. on 15M and 20M (the ant. was inside his bedroom at the time of the test).

http://www.io.com/~n5fc/notebk_ant.htm

Thanks,

No, it is a loaded dipole. It uses inductive loading
and top hat capacitive loading. "Linear", in this
context, means "evenly distributed" loading.

> Would you keep the wooden dowel form (for the coils), or would you let

I would use PVC pipe and run a Dacron "messenger line"
through the center for mechanical support.

For the coils, you will need approximately double the
length of the straight wire. Design the coils so you
can add or subtract turns. Or design the top hats to
be adjustable. Or adjust the length of the straight
wires.

The feedpoint impedance will probably be lower than
50 ohms. For single-band operation, coax will probably
work well with an antenna tuner.

> re-reflected.

Nope, Vf doesn't have to change for there to be a
reflection. Looking at what happens to the power
dissipation in the source resistor, Rs, when the
reflected wave arrives, we see that the energy being
supplied by the source drops by 99.85%. Most of
the energy in the forward wave is supplied by the
reflected wave, starting at the time the reflected
wave arrives and causes destructive interference.

> And yet it appears that you are claiming that power
> is reflected at the generator. How can power be
> reflected if voltage is not?

To be technically correct, reflected energy is redistributed
back toward the load during the process of destructive
interference.

The conditions before the reflected wave arrives and
after the reflected wave arrives are extremely different.

Before the reflected wave arrives, the source resistor,
Rs, is dissipating 25 watts.

After the reflected wave arrives, the source resistor,
Rs, is dissipating 0.03845 watts.

Clearly, something drastic has happened and that is:
99.85% of the forward energy originally supplied by the
source has been replaced with reflected energy being
redistributed back toward the load.

Because of destructive interference, reflected energy
never flows through the source resistor, Rs, and is
instead redistributed back toward the load.

Nothing else is possible since the source is supplying
only 1.9608 watts during steady-state. 92.3% of the forward
power is not being supplied by the source during steady-state.

The energy incident upon a point must equal the energy exiting the point. The energy incident upon the generator terminals is 1.92234 joules/sec from the source and 23.0777 joules/sec from the reflected wave. The energy exiting that point is 25 joules/sec. The reflected wave energy obviously reverses direction and joins the forward wave and that is what we call a "reflection".

You are getting out, however, by your low enthusiasm, it sounds like
you don't get much back in response for tossing out CQs. This may be
simply a matter of persistence because what you say more below
suggests not all is for naught:

>One good thing abt this antenna is, for it's size, it does receive
>better than the random-length wire (abt a 50' rectangle) I had been
>using inside my apartment. It does have good bandwith - but, as Roy
>stated this indicates low radiation resistance.

If you are receiving well, then you are not entirely boxed in - so to
speak (although it does sound like your apartment interior is shielded
by the building structure). You do sound like you have a lot of
height even if it is a air shaft.

Try an end-fed antenna (or work it against the ground of your three
prong plug). For that end-fed antenna, get a long fishing pole with a
reel full of flex-weave wire and a sinker. Mount the pole into a flag
mount so that it points out into the air shaft. Let the sinker loaded
wire drop into the shaft and drive the wire through your tuner.
Naturally, the longer the pole, the better - the more wire, the
better. Who knows, you might be able to tune-up by adjusting the
wire length. You can keep your existing antenna for listening (use a
T/R switch) and you are off and running. Don't worry about anyone
seeing it (especially at night) - they won't.

Cecil, get Feynman's _Lectures on Physics_ Volume I, and
read the entirety of Chapter 38, "The Relation of Wave and
Particle Viewpoints." Quantum mechanics is a very successful attempt,
using statistical methods, to explain the behavior of very small things.
In order to do that, it has to look at those things in very strange
ways. If you want to read about the philosophical underpinnings
you should read chapter 8 of _Quantum Theory_
by David Bohm (a Dover reprint).

Are you sure? I thought a reflection was something that
occurred at an impedance discontinuity and the magnitude
of the voltage reflection was defined by

Vr = Vincident * ReflectionCoefficient
= Vincident * (Z2-Z1)/(Z2+Z1)

and that the reflected voltage then added to any wave
already travelling in that direction.

But you are claiming that power can be reflected when
voltage is not. I have never encountered this claim before.

Are you sure?

...Keith

That's true for normal reflections which involve only
one wave. Wave cancellation is a different kind of
energy reflection involving two waves. The energy flow is
canceled in one direction and therefore flows in the
other direction. In optics, it is known as a redistribution
of energy in directions that allow constructive interference.
In a transmission line, there are only two possible directions
so any redistribution of energy due to destructive interference
can be considered to be a reflection in the opposite direction,
the only direction available to constructive interference.

> and that the reflected voltage then added to any wave
> already travelling in that direction.

True for a single wave reflection. For two interacting
waves, the voltage in one of the waves can simply replace
the voltage in the other wave. In our example, the reflected
voltage simply replaces the source voltage component.

> But you are claiming that power can be reflected when
> voltage is not. I have never encountered this claim before.

When the reflected wave arrives, it cancels most of the
existing forward wave from the source. The reflected
voltage exactly equals the canceled source voltage in
our example because the source resistance is the same
as the Z0 of the line.

> Are you sure?

It is obvious that reflected energy never flows in the
source resistor so it must go in the only other direction
possible. Yes, I am sure. The conservation of energy
principle will allow nothing else.

Brian
You have my undivided attention on this one. Can you steer me to a design for the Cubical Quad that you were referring to? I have all of the parts for a three element quad out in my shed. It came to me from the clean off of an antenna tower removal. I'm unfamiliar with the merits of that antenna but I am interested. The Forty Two Foot Tower will probably end up at field day this year if I don't sell or trade it but that will have the tribander three element beam on it. I am planning to have a forty eight foot mast comprised of 1/4" wall thickness two inch tubing and I was looking at the Spiderbeam as one possible choice for the antenna on it. The original plan was to use the mast for stacked VHF UHF array to go after the extra points available by working those bands without changing our class. This because a VHF / UHF station's contacts count but the transceiver does not count as a station for class. The reason I was looking at the possibility of another beam was that our GOTA station will need a directional antenna that it does not have to share with the Two HF Stations. That begs the question of what will I mount the VHF / UHF stuff on but I digress.

OK, thanks... The stacked dipoles was actually my first idea when I
started thinking about it a while back. But then I wondered if the
collinear would work. I guess there's a reason why nobody has done
that before. I do believe I've seen some fat stacked dipoles before
though.

100 cos(wt) 50 ohm line / 1 ohm
50w \ load
| |
+--------------+----------------------+
gnd
```

As a matter of interest, let's return to the 45 degree line, the one to which I objected previously.

The forward power and reflected power are the same as in the previous example but now the dissipation in Rs is equal to the sum of the forward power and reflected power. (It would be nice if all cases were as straight forward as this special case.)

This is indeed the one special case where everything you have been saying is true. There is no redistribution of energy because there is no interference. There is no interference because at Vg, Vfor and Vref are 90 degrees out of phase.

These concepts are covered in my magazine article at:

http://www.w5dxp.com/energy.htm

heh. more hype from the TV industry to separate fools from their money.
the truth is, all you need is a standard UHF capable TV antenna (as this is
where most if not all the DTV/HDTV signals will be present).

A standard vhf/uhf mast mounted antella will work for nearly 99% of all
urban environments in large urban centers.

not sure that such a thing exists. However, the ARRL has some nice
publications on UHF style antennas.

I only see one newsgroup on his post so I don't know why you say 'spamming several newsgroups'. He takes the time to post to each group individually if he appears in other groups. Also, he is not selling anything. Why do you call this 'spam', just because the guy wants to show people his website? Why do you have this tendency to attack other hams, bro? Chill.

Oops. There's some confusion here but I don't know which one of us is confused Tom. Maybe both of us. I wasn't referring to a specific quad. My point was that any properly tuned unnamed generic quad should be a better-performing antenna than a Spiderbeam. However the usual HF quad is not a lightweight antenna, they're designed/built to take a beating out in the weather for the long run and as you know fiberglass ain't feathers.

However for applications like dxpeditions, Field Day and other temporary locations where weight matters one should be able to design/build a very lightweight quad by using small diameter spreaders which would not be acceptable for use in permanent antennas. If done right a "portable quad" ought to be able to compete with the Spiderbeam as far as weight is concerned.

Now consider this! When a quantum of energy, of any wavelength is emitted from an atom or a nucleus then time and space ceases to exist for that "wave packet" until it is absorbed again, or passes through a medium where the velocity of light is less than c (glass for example, or coaxial cable!!!). Since it is always travelling at c in "space" then time ceases to pass for the quantum and/or the universe appears to be a single point from the quantum's point of view.
A possible corrollary of this might perhaps be that there is only one "real" quantum of a particular energy in the universe at a time!!!
This is pretty well where Relativity leaves Quantum Mechanics I reckon.
Now this may be philosophy but what is the answer that both quantum mechanics and relativity have for this apparent absurdity?
If it perhaps not so absurd, perhaps this explains some of the results of the famous single quantum slit experiment?
BTW surely FTL communication only destroys causality if the speed of information is infinite. Just faster than light by say 1,000 times would simply mean that it got there faster not before it was transmitted?

From: "Bruce W. Ellis" <ellis@means.net>
Message-ID: <lubsq35e6iv4hk0c8js6foktqpsf5movee@4ax.com>
Source record: 28168

I am considering a horizontal loop antenna that would be "squarish" (depending on tree locations) and about 400' in circumference. My (automatic) tuner is located in my garage (with 100' of coax going to the shack in the house). The lead wires for the antenna and ground are short and direct through the garage wall - I don't envision any feedline from tuner to the wire loop. I don't want to use a balun since there isn't really any feedline to balance and the impedances presented to the balun would be all over the (Smith) chart. Would it make sense to feed one end of the loop from the tuner and connect the other loop end to the ground connection near the tuner or just leave it open (essentially a square longwire antenna)? I would also have three counterpoise wires following the loop lying on the surface of the ground. The articles that I can find all use openwire feedlines and balanced tuners (or baluns) but that arrangement doesn't fit my situation. Thanks W0BF

Hi Bruce,

Well, in fact you have described a feedline - the one going to the
automatic tuner. This one has every need for choking as any line that
left the tuner (which is, by and large, not recommended by most
automatic tuner vendors). You probably also have DC power or control
lines going to that tuner as well. They need choking too.

However, given you also mention a 100 run, then this presumably means
along or under ground. Ground proximity would probably snub any
Common Mode currents which would then reduce your specific need for
choking.

>Would it
>make sense to feed one end of the loop from the tuner and connect the
>other loop end to the ground connection near the tuner or just leave
>it open (essentially a square longwire antenna)?

You might want to make it switchable.

>I would also have
>three counterpoise wires following the loop lying on the surface of
>the ground.

This technique falls outside of the canon of most lore, but not
without its benefits. However, three wires will not provide much
efficiency gain. On the plus side, it could make a difference for
NVIS.

You don't mention much about frequencies of operation nor about
directionality.

>The articles that I can find all use openwire feedlines
>and balanced tuners (or baluns) but that arrangement doesn't fit my
>situation. Thanks W0BF

You have enough to work with as it is. As for openwire or coax feedlines; to my knowledge, autotuners are built to feed unbalanced antennas directly (at the feedpoint) rather than as traditional hand adjusted tuners being used away from the antenna. This is, perhaps, a bias from seeing too many SGCs. Anyway, I don't see a downside to your plan.

Hi Cliff,

You have contradicted yourself. Your second sentence above has the
premise there is no time. Your last sentence ends with time
explicitly allowed.

>This is pretty well where Relativity leaves Quantum Mechanics I reckon.

How so?

>Now this may be philosophy but what is the answer that both quantum
>mechanics and relativity have for this apparent absurdity?

The contradiction offered.

>If it perhaps not so absurd, perhaps this explains some of the results
>of the famous single quantum slit experiment?

Dismissing absurdities, the single slit experiment has its own
explanation.

>BTW surely FTL communication only destroys causality if the speed of
>information is infinite.

As the lawyers would say "FTL communication" is a fact not shown in
the evidence offered here; so the rest of the statement does not
logically follow.

>Just faster than light by say 1,000 times would
>simply mean that it got there faster not before it was transmitted?

It would be more meaningful to demonstrate it got there 1.00000000001
times faster. If you cannot establish this mark, 1000 time faster
isn't on the horizon.

As one other poster was abashed to discover, you probably could witness that first demonstration if you were a fish. A fish swimming in the cooling pond of a nuclear reactor would be hit by a neutron (one bit of information) before the radiation (light, the other same bit of information) that catapulted it from the pile. Now, getting that neutron up to 1000 times faster (in terms of information flow) is unlikely; but if you were to choose to inhabit a pool of somewhat greater density (1000 times more so?) - then perhaps arguably so. I don't think we need hold our breaths and wait for AT&T stock to mature into Billion$ on that idea.

2099. Zo of two wire open line

Newsgroup: rec.radio.amateur.antenna
Date: 2008-02-10 00:08:33 UTC
From: Owen Duffy <none@no.where>
Message-ID: <Xns9A40713B6BDEAnonenowhere@61.9.191.5>
Source record: 28171

I have found two common expressions for the Zo of a two wire line in space.

One expression is Zo=276log(D/d).

The second is Zo=120acosh(D/d).

I have been searching for information on whether the acosh expression takes into account proximity effect. Because it does not consider conductivity or permeability of the conductors, one wonders if it does.

Laport has a graph that shows the log expression and a proximity corrected line which turns out to be a very close fit to the acosh line over the range that he plots. The curves are compared in http://www.vk1od.net/balun/Ruthroff/R07.png .

I have another reference, Marchand (1947), which gives the log expression then, the acosh expresssion and says "The hyperbolic cosine is obtained because the currents are attracted to one another and become more and more confined to the inside surface as the wires are brought closer together."

This suggests (states) that the acosh expression (fully) accounts for proximity effect on Zo.

Comments?

Owen

I must be doing something wrong. 276log(2)=83 but looks like about 150 on
your graph. No?

Sorry, that expression should be 276log(2D/d) for a consistent meaning of D
and d. (Some people use wire radius and some, diameter... so D here is
centre to centre distance, and d is diameter.)

Hi Owen,

I have the following expressions found in "Reference Data for Radio
Engineers," 22-22 Transmission Lines:

Zo = 120 acosh(D/d)
Zo ~ 276 log(2D/d)
Zo ~ 120 Ln(2D/d)

where the symbol ~ means "approximately equal to."

Thanks Richard.

Yes, I saw those in that publication.

ln(x) is a good approximation of acosh(x) for large x, so that explains one approximation, and the log expression is just a scaling of the ln expression.

I put some importance on the difference between the approximately equal and unqualified equal signs.

If the acosh expression fully accounts for proximity effect, it is interesting that it is independent of frequency, conductivity, and permeability. It would be nice to find a derivation.

I think if you derive C and L from first principles, you don't get the same curve as acosh... which suggests that acosh is account for something that L and C from first principles (assuming uniform current distribution) doesn't.

Owen

Brian
I'm afraid that I'm the one that was confused I was hoping that you had a specific design in mind. I have all of the parts for the one that was on the site of the clean off that I got a forty two foot tower from but I got it disassembled. It just needs a plan for reassembly. I guess I will have to ask around at the club and find an antenna Elmer that would be willing to help with guiding the reassembly so that we can test it well before field day. I've forgotten so much in the thirty years I have been out of Radio that it is almost like starting over.

Thank you very much for that link. I'm sure that will come in mighty handy as field day plans go forward.

Source record: 28178

The acosh formula includes the effect of skin effect on inductance and capacitance(*), while the simplified log formula is equivalent to considering the currents concentrated along lines at the conductor centers. Neither includes proximity effect.

Derivations of the acosh formula can be found in Johnson, _Transmission Lines and Networks_, Sec. 3.8; Chipman, _Transmission Lines_ (Schaum's Outline Series), Sec. 6.6; and other references.

I'm sure that a formula taking proximity effect into account would be much more complicated, judging by approximate formulas I've seen for calculating resistance change due to proximity effect.

From Chipman (p. 114), about the lack of published coverage of proximity effect:

"Fortunately, the combination of circumstances that would require accurate information about th eproximity effect factor for distributed internal inductance occurs rather rarely in transmission line practice. The most unfavorable situation would be a parallel wire line with solid circular conductors, the facing suraces of the conductors being separated by only a few percent of a conductor radius, operating at a frequency to have a/[delta] have a value near 2. These conditions make the distributed internal inductance comparable in magnitude to the distributed external inductance, with a proximity factor that might be as small as 0.8 or 0.85. There is no recognized basis for making an accurate analysis of the total distributed inductance of a line for such a case.

. . . When the facing conductor surfaces are at least a conductor diameter apart (s/2a = 2), the distributed internal inductance will be less than 20% of the total distributed inductance, and the proximity effect factor will me not less that 0.87. . . Proximity effect can then not modify the total distributed inductance value by more than about 2%, and the factor need be known only very roughly. . ."

(*)And even this is a high-frequency approximation which assumes that the conductors are at least several skin depths thick. Expressions for line inductance without this assumption involve Bessel functions, which I assume would also appear in expressions for Z0.

Sorry, I clicked Send before fixing up my typos in the Chipman quotation. Here's how it's really written:

"Fortunately, the combination of circumstances that would require accurate information about th proximity effect factor for distributed internal inductance occurs rather rarely in transmission line practice. The most unfavorable situation would be a parallel wire line with solid circular conductors, the facing surfaces of the conductors being separated by only a few percent of a conductor radius, operating at a frequency to have a/[delta] have a value near 2. These conditions make the distributed internal inductance comparable in magnitude to the distributed external inductance, with a proximity factor that might be as small as 0.8 or 0.85. There is no recognized basis for making an accurate analysis of the total distributed inductance of a line for such a case.

. . . When the facing conductor surfaces are at least a conductor diameter apart (s/2a = 2), the distributed internal inductance will be less than 20% of the total distributed inductance, and the proximity effect factor will me not less that 0.87. . . Proximity effect can then not modify the total distributed inductance value by more than about 2%, and the factor need be known only very roughly. . ."

(*)And even this is a high-frequency approximation which assumes that the conductors are at least several skin depths thick. Expressions for line inductance without this assumption involve Bessel functions, which I assume would also appear in expressions for Z0.

Hash: SHA1

I've made some Al foil cap. hats for a 34ish foot linearly loaded dipole (based on NN0F's antenna in the ARRL Antenna book, 21st ed, p. 6-35 - he used 6ft wires as cap. hats and 450 ohm ladder wire as the radiator, w/ coax feed). I was wondering if Al foil has enough "umpffh" to act as cap. hat material?

Cap hat construction: 45 inch cardboard rolls wrapped in 1-1/2 layers of Al foil (shiny side out). 300 ohm twin-lead (the ant. radiator) leads soldered to copper tape, which was stuck to the Al foil (I check for continuity between the foil & the copper tape & between leads & Al foil they were OK). Final version wrapped in clear packing tape.

I attached this ant. to my Elecraft K1 & got 4.7:1 SWR on 80 meters (where I expected it to resonate). On 15 meters got 1.2:1 SWR. Ant. is abt 45 ft above ground, fed by RG58 coax. Ground is concrete. Actually, the ant. is on my apartment bldg roof. That roof is covered in a silver paint or metallic weather-proofing (I don't know). The ground surrounding the apartment bldg is concrete and asphalt. I always select "Very poor - cities, industrial" as a ground description when using the EZNEC pgm.

Thanks for any comments.

Aluminum foil is fine for the purpose, electrically, but I think you'll have a dickens of the time maintaining good contact to it. You might even end up creating a rectifying junction which could generate harmonics when transmitting and intermod when receiving.

news:13qsrn4ga5j7cfa@corp.supernews.com:

Thanks Roy.

I was suspicious that proximity correction could ignore conductivity, permeability, frequency and the actual diameter and distance.

Chipman paints a picture that it is pretty messy mathematically, and the flow into Zo would be really messy.

What I do glean is that for D/d>2, the error is small. That is a whole lot better than the log formula which is poor for D/d<10.

I have two immediate applications, one is a model for a 1:1 choke balun (http://www.vk1od.net/balun/Guanella/G.1-1.htm) and the other is yet another transmission line loss calculator, along the lines of my existing calculator that is aware of about 100 standard transmission line types, but this one allowing specification of an arbitrary two wire line (http://www.vk1od.net/tl/twllc.htm).

For the balun cases, I am very interested in D/d<<2.

I think I will continue to use the acosh expression, and let it calculate without limit on D/d, but qualify the results with a note that proximity effect is not included in Zo, Zo is underestimated for D/d<2 and the error may be significant.

Roy, thanks for your time to research and type the notes up.

With all due respect, this is not correct. From the quantum's point of view,
time passes as it normally does when moving at c. From the observer's point
of view, the time that the quantum is experiencing is zero relative to the
time that the observer is experiencing. If your twin brother moves at c for
twenty years, your twin will experience time as normal in his own frame of
reference but in your frame of reference as an observer, he will be twenty
years younger (and would look it too). Part of the dilemma is that he should
have 20 years of memory in hisown time frame but when he returns back to
this time frame it will seems as just an instant has passed.

> information is infinite.

No, FTL communication itself does not destroy causality. However, if it involves mass or quanta in motion between point A and point B, those entities must behave according to causality which means basically that they can never travel faster than c. Thus, FTL "communication" cannot involve the motion of such entities. At IBM a few years ago, theories began to arise in their R&D labs in Switzerland about super fast communication that could travel 7 or 8 times c or even more. It doesn't involve motion of mass or photons or fields (or certainly not electrons or holes), rather it involves statistics. For example, suppose I have a pair of quarks where if one is oriented as top, the other must be oritented as top. Call this condition 1. Now separate the quarks and put one on earth and the other on say mars. Now, Everytime I reorient my top quark on earth to become a bottom quark (call this 0), then the quark on mars must, statistically, become a bottom quark (value = 0) in nearly zero time. Compare that against the 15 minutes that a light wave takes to travel from mars to earth. I know that a lot of theoretical progress has been made on communications by statistics using quantum theeory and subatomic particles and prototypes have been made. However, IBM has lately been investing less and less in R&D these days as it moves into becoming a software company. You may concede that FTL communication is already possible in this way and it does not produce a causality dilemma at all.

Richard, I think you are making a bit too much out of the nuclear reaction cooling pond event. It is not a paradox, causality is preserved. However, it does make for a nice light show.

What happens in the cooling pond is that the neutrons only move faster than light can move in the medium (water). If "c" is the speed on light in a vacuum, then even light moves slower than "c" in water. What does not happen is the neutrons moving in the cooling pond water faster than "c" in a vacuum. The equations that present causality dilemmas all involve "c" being the speed of light in a vacuum, which NOTHING can exceed.

Where delta T' = change of time experienced by a moving particle of velocity v.

and delta T = change of time experienced by a relatively stationary observer,

delta T' = (delta T)*(SQRT(1 - v**2/c**2))

Where c = the speed of light in a vacuum.

If v of the neutron = c in a vacuum (which it cannot), then it experiences zero time relative to the observer. The causality dilemma occurs when v > c (in a vacuum) and it is just as impossible to occur as it is impossible to have the square root of a negative number).

Source record: 28187

This might be useful:

King, in _Electromagnetic Engineering_, Vol. 1, says (pp. 467-8):

". . .the problem may be analyzed for wires sufficiently far apart and so small in radius that rotational symmetry in the interior and on the surface of each conductor is a good approximation, and then generalized to closely spaced conductors of large radius simply by writing

ae= a * sqrt(1 - (2a/b)^2)
be = b/2 * (1 + sqrt(1 - (2a/b)^2))

instead of a and b in formulas for the external impedance."

a is the wire radius, b the center-center spacing, ae is the radius to be substituted and b is the spacing to be substituted. He's saying that you can account for proximity effect just by substituting equivalent wires of smaller diameter and closer spacing which have idealized evenly distributed current around the outside.

He introduces the equation for ae earlier without proof, but references a 1921 paper in an obscure publication, as a way to adjust internal inductance for the proximity effect. The method is much simpler than the approximate equations for added loss due to proximity effect I've come across, so I suspect it's an approximation, but I don't know the applicability limits. But you might try incorporating it and see how it compares with measurements and with calculations based on the more complicated equations.

I see that when the wires are just touching (b = 2a), you end up substituting wires of radius zero, spaced at half the actual distance. I suppose that's reasonable.

Hi,
I have just been tuning a 400MHz 1/4 wave antenna (approx 170mm length of wire). I connect a receive antenna to a spectum analyser and the antenna to be tuned to the signal generators 50ohm output. I set the signal generator to 400MHz and adjusted the length of the antenna to get a maximum peak on the spectrum analyser. My question is when i have tuned the antenna for maximum output at 400MHz is the antenna then tuned to 400MHz or is the antenna's impeadance tuned to 50ohm or both?

Marcus,
I think the 'right' answer would be "both", sort of, since what you are doing is looking for the maximum signal strength. Since the input impedance of a 1/4 wave radiator isn't 50 ohms to start with, you are also doing some impedance matching by length of radiator adjustment. You seem to be getting the most benefit (signal strength) from using 'different' measuring devices than 'normal', but it's working, right? And when you think about it, that's what most people do when they 'tune' an antenna, just different measuring devices. 'Resonance' and impedance matching trade off, sort of. Is that the 'best' possible way to do it? Mmmm, no. Is it a practical way to do it? Mmmm, yes, sort of, if you've got the required devices.

Well, it could be, both, most times for practical use it's ok.

But antennas also have directional senitivity, and you may just
have optimized the direction diagrams for your experimental setup,
and not for DX wide distance connections. There is impedance match,
resonance and directional characteristics which we have to care for,
all three parameters!
The antenna may be in resonance, but Z not necessarily at 50 Ohms,
or it may have 50 ohms but be out of resonance and thus loose
efficiency and/or it may be radiating down to the earthworms.

Everything in the vicinity influences the impedance and resonance
parameters. Therefore normally we mount the antenna at it's proper
place, on the roof, on the mast or where we want it to use.
Then we measure either at the antenna footpoint or the bottom cable
end. I have seen people mounting an SWR meter at the antenna
in 10 meter height and then take readings with a telescope
from down under.

To optimize transmitter to antenna coupling we need a directional
coupler for 50 Ohm
http://en.wikipedia.org/wiki/Power_dividers_and_directional_couplers
and connect the antenna to the output port, the signal generator to
the input port, and the analyzer to the coupled port.
The isolated port must be terminated with a 50 Ohm resistor.
Then the antenna is optimally tuned for transmission when the
reflected signal gets to a minimum, that is, nothing is reflected back
to the analyzer.
The easier way is to use a SWR meter
http://en.wikipedia.org/wiki/SWR_meter where the signal generator is
connected to the input, the antenna to the output, and the reflected
signal is show on the meter instead of an analyzer.
This way we make sure the transmitter feeds all the power to the

transmitting antenna.

But where does the energy go?
Worst case, straight up to heaven.
We need a remote antenna to make sure we did everything right.

w.

Hi Don,

This has been pointed out by me in my own quote - so nothing new here.
However, the distinction of faster than light is simply that, and it
has been demonstrated. Instead, what you are arguing is NO-THING
travels faster than 299,792,458 meters per second. I will leave that
to others.

Hi Marcus,

You have tuned a system with a variable stub. To replicate its use in
a practical application, you would replace the generator with an equal
length line terminated in 50 Ohms shielded in a box the size of the
generator (with a dummy line going to the AC wiring to complete the
ground path). You would then have to replace the spectrum analyzer
with your transmitter/receiver in a similar sized box at the end of a
similar length of transmission line. Also during operation, you would
have to inhabit the same vicinity/volume of space as you did when you
clipped the wire. However, precision and resolution may not be that
demanding as you imply by asking for two places: 50 ï¿½j0 Ohms.

In other words, your work would suffer compounding issues of proximity
and parasitic relations - lack of isolation. As a quarterwave antenna
does not present 50 Ohms without extenuating factors, achieving that
figure away from the bench would be more luck than engineering.

Hello Marcus,

You method does not guarantee optimum match (hence maximum radiated power). Matching involves reactive component = 0, resistive component = 50 Ohm (for a 50 Ohms generator).

When your quarter wave wire (connected to RF generator) has a real impedance (Im(Z) = 0). The impedance can be anything between about 18 Ohm and > 50 Ohms. It depends on the termination of the coax shield at the quarter wave wire connection. So resonance (generally spoken, no reactive components), does not guarantee maximum power transfer.

Only when you can prove by other means that your quarter wave antenna is 50+j0 Ohms when in resonance, maximum reading on the analyzer corresponds to optimum match and maximum radiated power (assuming no ohmic losses in the antenna). As a first approximation, you can see the quarter wave antenna as a series resonant circuit with a series resistor that represents the "losses" due to electro-magnetic field radiation.

Best regards,

Wim

Hello Owen,

In electromagnetic waves & antennas (Orfanidis, paragraph 9.5), they calculate the electrostatic capacitance of a two wire conductor assuming the wires as equipotential surfaces (so no E-field components parallel to the conductor surface). This implies non-uniform charge distribution for close distance (so proximity effect). Also when you look in the graph, the charge centers are closer to each other then the center to center distance of the parallel wires.

From the capacitance you can directly calculate the characteristic impedance based on c0 propagation speed.

The exact solution (based on the capacitor approach) comes with the Acosh function. So I think that (some or all) proximity effect is taken into account. Off course they assume all charge on the surface, so skin depth << diameter of wire.

The formula with the "ln" is just an approximation for the "acoh" function when D/d is large. The acosh formula gives zero for touching wires. This is correct for the assumption that all charge is on the surface (so no magnetic field will penetrate the wires).

Hope this will help you a bit.

Best regards,

Wim

Do you have some reference for Einstein's personal confirmation?
Something distinct from his having presented a theory? The truth of
the matter is for Einstein's, "light" went slower than "the speed of
light" which historically, and following his major work, was 299,796
kilometers per second. This too, illustrates a speed at which
NO-THING travels faster than (not even light).

No doubt you have some reference to Einstein's later lab work (new
theory?) that eclipsed the accuracy of measurements by Michelson in
1926. Cherenkov's observation in the late 30s would further move the
goal post.

PMG, Course of Technical Instruction (old) says that the 276Log(2D/d) is inaccurate when the clearance between the wires is small compared with the wire diameter. The book goes on to say that the acosh formula is an accurate one for all spacings. No mention is made of efffects of skin depth et al on Zo.

The way the "Big Boys" do this is with an Impedance Bridge connected
to the Spectrum Analyzer, Tracking Generator, Antenna, and 50 Ohm
Termination Load. Then prune the antenna for the biggest NULL, at the
desired Operating Frequency. Been using this method for years on
MF/HF/VHF Marine Coast Station Antennas. sure takes the guesswork out
of the system.

Hi Roy,

Thanks again for the research.

I would have thought that current would distribute itself in the
conductors for the least voltage drop along the conductor due to
inductance and bulk resistance. That suggests that as the conductors are
brought very close together, one expects that Zo should decrease
smoothly(ie the Zo is a monotonically increasing funtion of distance
between conductors for all positive distance).

If I take acosh(be/(2*ae)), it has a minimum around be/(2*ae)=1.3.

In the expression ae= a * sqrt(1 - (2a/b)^2), ae goes to infinity as b approaches 2a. This would drive acosh(be/(2*ae)) towards infinity as the wires are bought together.

> I see that when the wires are just touching (b = 2a), you end up
> substituting wires of radius zero, spaced at half the actual distance.
> I suppose that's reasonable.

I think there are probably limits for use of these formula.

The turning point in the region of (2*ae)=1.3 concerns me. I cannot intuitively see an explanation for such a behaviour.

Richard, all you have to do is look ar the lorentz transformation, SQRT(1 -
v**2/c**2). The lorentz transformation is the basic for the special theory
of relativity. This "theory" has been confirmed by many experiments of which
I definitely could give many examples. I hope you are not challenging the
scientific credence of this "theory" which is really thought of as fact. If
I give you one example, then will you require two, then three and so on
(similar to the 'prove a negative' technique)? I don't think so. I think you
really do believe that the special theory is in fact, a fact accomplii.

Now, if I am to assume that you give high credibility to the special theory of relativity, then you give credibility to the loretz transformation that forms its basis (and which Michelson used himself). So let me take a big leap and assume that you believe the lorentz transfromation has a high probability of defining time dilation. If we can get that far, then by simple examination, velocities greater than "c" cause the nummerical value under the square root radical to become a negative number. As you know, this is an impossibility because the square of any number must be a positive, in the real world.

One experiment I will mention is an easy one, conducted at MIT. It was well known that cosmic rays were mu mesons that have a defined decay rate when resting still in a laboratory setting. When traveling they should have the same decay rate.Therefore, if you know the velocity of the mu mesons and you measure the density at the top of a high mountain, you should know how long it takes them to reach the bottom of a mountain and by knowing the time it takes, you should know the density (a smaller number) that you should measure at the bottom. However, the measurements of the mu meson densities at the bottom were nearly the same as at the top. When perhaps 40% less should have been measured as decayed, only a very small percentage had decayed, EXACTLY in accordance with the lorentz transformation as described above.

By virtue of the impossibility of having a real situation of the square root of a negative number, or time multiplied by "j" (SQRT -1), it is impossible for v to exceed c in the real world. I will admit that it could "true" in the "imaginary" world of "j". which is the same world as power that is not dissipated etc. etc.. Nobody in the business really believes in tacghyons or other such particles that allegedly exceed "c"....that is all X-files stuff and to be dismissed by real world scientists.

To all,

I don't know what Mr. Ring's problem is, but I'm sure that it is hard to spell. He sent me this email today falsely accusing me of something that I did not do. If anyone on this newsgroup knows him personally, someone needs to talk to him. Before I make phone calls myself.

KF4DNA

---------- Start of Tom Ring's Message To Me ----------

You will want to read the following carefully.

The federal government passed a law several years ago that makes your callsign equivalent to your name. For instance, you can legally sign a check with it.

You made an account on hotmail that is mine. That is probably identity theft. A federal crime, by the way. Proving it was you that did it is trivial. It's called logfiles and IP addresses.

I'm going to call a friend of mine in downtown Minneapolis who works on an internet crime task force, and whose title is "Special Agent". I'm sure he won't mind, as I spent an hour talking to him just last week. You see, I've done networking and systems for a very long time.

You might want to think for a while on how you might be able to avoid me making that call.

My view is that you have adjusted the antenna to accept the maximum power from your source which should in this case have an equivalent source impedance of 50+j0.

Contrary to popular belief, radio transmitters do not necessarily or even usually have an equivalent source impedance close to 50+j0.

You should not be surprised if you replaced the generator with a transmitter and performed the same procedure, that the optimum length might be a little different, and that if changed the feed line length a little, the optimum length might be a little different again.

You would more usually want to adjust the antenna to be within a given VSWR tolerance, and to know the final VSWR, you will need some form of directional coupler on the signal source to determine rho etc.

"...a fact accomplii." Look that one up in the dictionary.

"As you know, this
is an impossibility because the square of any number must be a positive,
in the real world." (O + j1)^2 is -1. (0 + j1) is part of the set of
complex numbers.

Anyone who won't use complex numbers in physical analysis is
going to have a hard time understanding physics texts, or, for that
matter, simple network theory.

The corollary to what you are saying is that a particular transmitter might put out more power when presented with a load other than 50 Ohms. Assuming the output is voltage limited, as to 13.8 V at the drain, more than likely a hot (high gain) transistor will put out more power into a lower impedance. This would also increase the temperature rise in the transistor.

Hi Dan,

Well, this is not confirmation merely exposition - and not even unique
to Einstein. It is demonstrated that v can exceed c (you have
replicated my observations there, so that cannot be in dispute), but
it cannot exceed 299,792,458 meters per second (which bares scant
relationship to complex numbers). This is not a remarkable
observation because neither can v exceed 300,000,000 meters per
second, nor 300,000,001 meters per second and so on.

It cannot. You have too broad of a definition of "c". See nelow.

(you have
> replicated my observations there, so that cannot be in dispute), but
> it cannot exceed 299,792,458 meters per second >(which bares scant

(sorry .... cut)

Looks like semamntics to me. Whenever you see "c" in the special or general theories, it means exactly 299,792,458 meters/sec. You should not use the designator "c" to express the speed of light in other media such as water. It will always be a smaller number. The designator "c", meaning "constant", is indeed a universal constant designating the speed of light in a vacuum. The lorentz transformation and resultant time dilation derivations have only to do with "c", i.e the speed of light in a vacuum, not the speed of light in water or solid acrylic, glass or any other media.

I must admit, you made a very good point, i.e. that in some media there are particles that travel faster than light can travel in the same media even if they can never reach or exceed 299,792,458 meters/sec in any media. But I will remind the reader that this in itself does provide any causality dilemmas or prove the existence of God because the universal constants (like "c") still hold true.Particles that travel in water faster than light travels in water still travel at a velocity less than 299,792,458 meters/sec so the quantity in the square root radical is still positive. However, it does make for a nice light show for tourists who visit nuclear power plants. I wonder if the tour guides are able to explain what I just said?

Message-ID: <13qvb0l75klaga4@corp.supernews.com>
Source record: 28109

You've gotten several answers, but let me add one more, from perhaps a little different point of view.

The question of whether the antenna is "tuned to 400 MHz" isn't an easy one to answer, because it doesn't have any real single meaning. As you adjust an antenna's length in the vicinity of a quarter wavelength, there's no magic length where the antenna is "tuned" to work better than for another length. You can change the length a fair amount in this region without having any appreciable effect on the pattern or gain. So your adjusting isn't impacting the pattern or gain of the antenna to any appreciable degree.

What you are doing is changing the impedance at the base of the antenna. That impedance is transformed through whatever length of transmission line you have connected to it, and that transformed impedance is what the signal generator sees. The signal generator, having a fixed output impedance of 50 ohms, will deliver the most power when it sees 50 ohms resistive, causing the spectrum analyzer to show the maximum received signal. So what you've done is to adjust the antenna feedpoint impedance so that, when transformed through the line, it provides the best match to the signal generator output impedance of 50 + j0 ohms. You could say that the antenna itself is "tuned to 400 MHz" when its feedpoint is purely resistive (that is, the antenna is resonant). If you have a perfect 50 ohm match at the signal generator, then you know that the antenna impedance is 50 + j0 ohms (assuming you're using 50 ohm transmission line between the generator and antenna). But if you don't have a perfect match at the generator, the antenna might or might not be resonant at the point where the match at the generator is best. In practice, for a 1/4 wave antenna, it'll be very close. But as I said in the beginning, that's of really no importance in determining the antenna performance.

If you were to put an adjustable matching network between the signal generator and antenna so you could assure that the signal generator always sees 50 + j0 ohms, you'd find that the antenna length adjustment (over a moderate range) has virtually no effect on the received signal strength as long as you adjust the matching network for maximum received signal after each length adjustment. But most VHF transmitters and receivers are designed to work with a 50 ohm load and don't have any built in adjustable matching capability, so the adjustment you've done will result in the best overall performance when connected to such a transmitter or receiver.

From _Latin For Today_ by Mason D. Gray, and Thornton Jenkins (1927),
Celeritas; speed, swiftness.

(In the flyleaf is written in a female hand:

Latin is a dead language.
It's as dead as it can be.
It killed off all the Romans.
Now it's killing me.
-Shakespeare-

Any gedanken experminent involving a mass with a velocity being greater than 299,792,458 meters/sec leads directly to the quantity under the square root sign for (1 - v**2/c**2) [where c = 299,792,458 meters/sec] to become a negative number. Impossibly absurd. So there you have it. The gedanken experiment involving FTL has been performed and the result of the challenge as to whether it can happen is reductio ad absurdum. Impossible. We cannot have the square root of a negative number in this universe.

QED ;-)

de AI4QJ

I will give you that one! In these case I must have assumed all these years that "c" was for "constant" but your explantion is probably much more

accurate and certainly more colorful.

What do you mean "maintaining good contact to it"? The copper tape adheres well & doesn't move. The foil is secured in place by the packing tape (it completely covers all of the foil surface and copper tape connections). The tubes propeller a bit in the wind, but I don't think that causes any disruptive flexing of the foil; at least not enough to cause the soldered/taped connection to break/discontinue.

I couldn't xmt on 40M cause of the high SWR, but I could rcv &, except for the noisy conditions, it sounded fine.

Thanks for your comments.

We have progressed from your statement that:
>>> Instead, what you are arguing is NO-THING
>>> travels faster than 299,792,458 meters per second. I will leave that
>>> to others.
>>
>>Correct. However, why don't you just leave it to Einstein who has confirmed
>>this, rather than leaving it to others, particularly a bunch of ham radio
>>operators who sometimes have their own 'theories' ;-)
to an absurdity where at the time of Einstein's theory (or in the historical neighborhood of 1926 which I have pegged at Michaelson's most accurate determination) that light at 299,796 kilometers per second most certainly is a speed sufficiently in excess of the speed of light (by later accurate determinations), and yet this present speed proves nothing could exceed the speed of light (begging the question, of course, which speed of which light) whereby we are inescapably faced with the prospect of a negative number dashing one proof of Einstein's or another (the same one?).

For those confounded by the turns in the road for a varying constant (you have every reason to be confused): The speed of light in 1926 clearly results in a -1 solution for today's speed of light proving that light traveled faster than the speed of light in 1926.

Imagine the egg on Einstein's face for thinking c = 299,796 kilometers per second for the identical gendanken experiment at its inception so it appears that -1 has no particular significance rooted in a fundamental law to be so accommodating to a wide variety of assigned constants for the identical, immutable law of the universe. It would only take another measurement, adding a jot to the decimal place, to dash all other proofs which hinged upon those prior determinations. It would be safer to simply express that NO-THING can travel faster than some suitably buffered number with a margin added such as 305,000,001 m/s (ï¿½3dB). Something that a greater number of reasonably minded folk could agree with (or simply bump the number higher to achieve consensus).

Summing it up: a negative outcome seems to be more fashion than proof if the logic follows the historical whim of error.

So, as to your assignment to Einstein's confirmation of "this." What "this" were you speaking of, when was "this," and which Einstein?

Ah Richard! I see where I didn't make myself clear.
There are 2 points of view here (or 2 observers).
For the mythical observer on the "wave packet" as special relativity
tells us, at c time ceases to pass. The corollary of this is that the 40
million years it takes a quantum of light from M104, for example, to
reach my eye at the eyepiece of my telescope does NOT exist from the
Quantum's point of view. Or from another aspect the space between the
galaxy and Earth doesn't exist from the same point of view since it was
traversed in zero time.
From my point of view at relatively zero velocity there is a 40 million
LY gap to traverse in ~40MY but surely if special relativity is correct
this is not what the quantum "experiences" at all. Presumably it
"experiences" emission from an atom in M104 and absorbtion by an atom in
my retina as extremely (perhaps 2x Planck times) close events, unless it
passea through a medium in which the velocity of light is less than c on
the way.

Certainly I agree with you that electromagnetic radiation cannot travel
faster than c in this universe. But that is not to presume that other
forms of energy tranfer may not be possible at higher velocties.

A possible example is "gravitational radiation" which although it is one possible explanation for certain astrnomical phaenomena has NOT yet been detected. My research into such instruments as LIGO shows that a major factor in the hoped for detection is an assumption that this radiation travels at c. This is neccessary for correlation of signals and observed events. If this quadrapole radiation travels at some other velocity then null results are just what one would expect.
The null results of SETI do not surprise me for a similar reason. If there are advanced starfaring races out there radio or other EM communication would be woefully inadequate and either not used at all or only for very specialised (and slow) directional links which are unlikely to send data towards Earth. If not then we are just an anomally and we won't be around for long enough to matter on the cosmic scale.

The instant aluminum comes in contact with air, an oxide layer forms on it. The oxide layer is a hard, brittle ceramic which is an excellent insulator. Making electrical contact to aluminum requires breaking through the oxide to the metal underneath. This causes broken pieces of the oxide to dig into the aluminum. If pressure is maintained and no air ever strikes the aluminum again, the contact will remain sound. That is, in fact, how aluminum house wiring is (properly) handled -- a high pressure contact, with a generous amount of grease to prevent contact with air.

If your contact jiggles a bit in the wind or for any other reason, the physical contact in various places will be broken at times. Each time, more oxide is formed and, when pressure is reapplied, it breaks and gets pushed into the aluminum. Eventually, you have a surface that's mostly shards of oxide and little or no metallic aluminum. (This is also why tin plated contacts always inevitably fail.)

In addition, copper and aluminum form an electrolytic cell. So if any moisture is present, corrosion of the joint will occur and contact will eventually become bad or lost altogether.

That's what I mean by the difficulty of "maintaining good contact". Your system will work fine. For a while.

I would like to point out as a former Assistant RACES Officer for a local community in Massachusetts, that Mr. Romney is absolutely correct.

The current EMA-ARRL structure co-exists with the STATE RACES Officer and going nothing.

ARES has nets that do NOTHING. RACES does nothing. 85% of the communities south of Boston do not have any active participation in the RACES drills.

One of the studio engineers was a ham and threw out the question to Jacobsen as something to hit Mr. Romney.

Frankly, MEMA is much better organized than everyone would think. A total communications melt-down is impossible in Massachusetts due to MEMA, SP and SG preparations. The Air Wing is ready to roll out portable towers for cell phones. The SP has several rolling CC and backup towers for the 800 Mhz system. Each town has the 800 Mhz radios provided by the state.

Just so you know that some of those guys actually doing things are HAMs. They learned by being hams. Yet, we don't need hams as a massive fodder to materialize for the day of rescue. I would like to think Mr. Romney is right about this as we are paying our TAX DOLLARS for service!

If I was a member of an advanced race, I would be using
entangled particles for FTL communications. However, I
would also be listening for those primitive slow obsolete
EM waves.

10: 7.1 dBi gain

full-size 2 el quad (from www.cebik.com)

6.8-7.2 dBi (at freq where f/B is peak, also depends on boom length)

I'd say in practice they are pretty much equal...the quad being three-
dimensional will be much harder for one or two people person to put up.

Hi David,

And thus it follows that Michaelson's "faster than light" speed is due to the effects of the atmosphere? I would believe from the conventions offered by Snell's law, predating this work, that all the scientists would have been astonished at this inversion of expectations.

But we know better. The speed of light's shift in speed would have been far in excess of the difference found between 1926 and 1956, if due to the presence of the atmosphere - and its effects were well considered at the time.

No, this is simply a matter of experimental error as the range of speed has over the years tightened. However, all of this begs the issue why would Einstein's work (theoretical not experimental) pivot on a number that fluctuates with time, over time? In fact it does not, and Einstein did not confirm the speed of light, nor did his theory preclude nor deny Cherenkov's observation of solid matter (neutrons albeit) traveling faster than quite obvious light (irrespective of how fast it was "defined" to travel). Einstein has not been limited to the vagaries of observation from any experimenter and that is his accomplishment.

Actually there ARE numerous VHF TV stations running digital (HD) today,
right along with their SD NTSC broadcasts on a different channel. In
Cleveland OH all the major networks have their HD on the air in addition to
analog, though not all of them are broadcasting digital on the channels they
will use starting Feb 17, 2009. Asd an example, NBC is analog on 3, digital
on 2 today; their digital will move to 17 during the cutover and both 2 and
3 will be abandoned. FYI, the FCC has advised the cable companies that they
are required to carry the HD as non-encrypted ATSC, in addition to analog.
Both have to be in the basic tier of channels. Some digital TV
manufacturers sets, but not all, include the ATSC cable HD 1080 digital
modes in their built-in tuners.

What is the antenna length?

Now as for Al foil as an antenna construction material:

It works electrically, but isn't very strong. Your cardboard tubes
aren't terribly weatherproof either. You might be able to shellac them
heavily. But still it isn't a very good choice.

Making contact with the aluminum could be an issue. Tubular aluminum is
used on antennas, but the connection is usually helped by corrosion
inhibitors, and nuts/bolts with washers to help "dig in" to the AL. Your
thin foil will deform at best, and more likely rip with that sort of
treatment.

I would further speculate that the odds of the "as deployed" performance
(in a temporary portable/field erection) of the quad being what the
model says are lower than for the Spiderbeam. The quad is bulkier and
3D, and deformations and environmental effects might be more of an issue.

Or with their handy dandy Vector Network Analyzer, which essentially
rolls all of the above stuff into one convenient package. There's a
fair number of mfrs selling VNAs targeted to this kind of market (i.e.
standing out in the wind on a tower, as opposed to in a nice quiet
anechoic chamber indoors). There's some nice stuff for antenna ranges
too (fiber optic connections to the remote measurement point, for instance).

Hi Cliff,

Yes.

> From my point of view at relatively zero velocity there is a 40 million
>LY gap to traverse in ~40MY

Yes.

>but surely if special relativity is correct
>this is not what the quantum "experiences" at all.

Experience necessarily connotes a "before" and "after." There must be
some interval of time. Hence quantum, by your first observation,
cannot experience anything as everything is simultaneous.

>Presumably it
>"experiences" emission from an atom in M104 and absorbtion by an atom in

The time to convert a photon to a photochemical response runs to
several femtoseconds.

>unless it
>passea through a medium in which the velocity of light is less than c on
>the way.

That would have nothing to do with anything, except for a second
observer who is the only one to gain by "experience."

>Certainly I agree with you that electromagnetic radiation cannot travel
>faster than c in this universe.

And it would be remarkable if it did seeing it is light anyway.

>But that is not to presume that other
>forms of energy tranfer may not be possible at higher velocties.

That has already been demonstrable for 70 years. However, what has
been demonstrated was perfectly within the context of pre-existing
theory, math, and experimental observation.

>A possible example is "gravitational radiation"

Coining new terms where gravitation already has a body of science
behind it does not further the dialog.

>which although it is one
>possible explanation for certain astrnomical phaenomena has NOT yet been
>detected.

An unusual comment given it is an ordinary experience available to
even the tribesman of sub-Saharan Africa.

>My research into such instruments as LIGO shows that a major
>factor in the hoped for detection is an assumption that this radiation
>travels at c.

What you are talking about is gravity waves (let's at least use the
terminology of research rather than substituting in "radiation" to no
obvious gain). There are those who would say it is instantaneous
throughout the universe, and does not propagate at all. Hence the
inability to detect them.

It kind of goes with the old real estate saying that they are not
making any more of it (land/gravity).

>This is neccessary for correlation of signals and observed
>events.

Neither of which have been detected. Do you note a contradiction
here?

> If this quadrapole radiation travels at some other velocity then
>null results are just what one would expect.

But by your earlier statements, there are some who do not expect this
at all. Given the contrary positions, neither of which that can be
proven, much of this is fevered thinking.

>The null results of SETI do not surprise me for a similar reason.

No reason has been proposed.

>If there are advanced starfaring races out there radio or other EM
>communication would be woefully inadequate and either not used at all or
>only for very specialised (and slow) directional links which are
>unlikely to send data towards Earth. If not then we are just an anomally

Well, this has scant relation to the start of the post, except both suffer from lack of demonstrables. There is an infinity of negative relations that cannot be supported, and these are only two of them. Sounds like the beginning (or ongoing) of entropy.

Hi Roy,

If I recall history and physics correctly (and simultaneously), house
wiring failed through cold flow, a property of aluminum to relax under
a one-time application of pressure (impulse rather than sustained
pressure) and thus the joint failed. The failure raised resistance,
resistance raised temperature, temperature raised flames.... no more
common use of aluminum in house wiring.

When I put in a new service entrance in 1979, it was after the problems with ordinary aluminum house wiring were discovered and it was no longer being used. But the service entrance cable I got was aluminum. The service box connectors are marked as approved for both aluminum and copper wiring, and have a compression fitting which doesn't give the aluminum anywhere to flow. Generous application of NoAlOx or a similar grease was also required for proper installation, so that's what I did. It's been completely trouble-free for nearly 30 years now. So it was, and is, possible to use aluminum wire. But it has to be done correctly, with due regard to its vagaries.

The antenna is abt 34 ft (1/4 wave for 40 meters).

The cardboard tubing was for weight - this ant. was to be a portable
ant. and would be deployed only in good wx.

"Treatment" - that's why I wrapped the tubes/foil in clear plastic
wrapping tape. Barring me accidentally smashing them or some
discombobulated squirrel "having at 'em" I'd expect them to last for abt
a year or 2.

2167. Another Stealth Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2008-02-11 22:10:50 UTC
From: Swoozie Pellegrino <swooziep@yahoo.com>

Hi, all.

I'm about to become a General class licensee, and I'm
trying to work out a HF antenna plan for my new apartment.
I have a small balcony on the top (4th) floor, which is good,
but unfortunately there's a roof overhanging it and is
8' over the balcony floor and juts 4' out over the balcony edge,
so a tall vertical is out of the question.

What about a 'vertical' that is angled about 45 deg. down
from vertical? Will that be good for phone DXing on any
HF band?

Also, sadly, the balcony is all metal and so is the top of
the roof.

What about some kind of loop?

Thanks!

~swooz

Roy;

The problem with AL house wire is that the pure Al that the wire is made of will flow under pressure. When it was used with Cu wire switches and outlets the attachment points could not maintain the pressure to insure adequate contact.
At work one day the personnel department secretary requested one of the company two way radios for her desk. I installed a Motorola HT220 in a desk charger and plugged it into the outlet next to her desk. That night the mobile home trailer that we used for personnel burnt to the ground. To this day I don't know if there was a connection. ;^)... However, the radio was a mess. The trailer was manufactured during the copper shortage that necessitated the use of Al wire.

Is there a method for getting the SWR sweep data from EZNEC into an S- or Z-parameter format for use in another application? Please forgive my relative unfamiliarity with this part of EZNEC.

Thanks very much,

Al

Well Cecil, you might be listening, but I might not be sending!
It often amuses me to consider just how naive humans can be in
advertising their presence in our spiral arm for a long time now.
Why do so many assume that an advanced race might have such a benign
attitude to other intelligences. We probably don't even share DNA
so why should we seee things in the same light.
See Larry Niven's "Tales of known space" (about 1966) for an example of
a race that got more than it bargained for when it met the Kzin through
radio.
Cliff Wright.

I think this is the "real" reason that the FCC tells us to use only the
minimum power necessary to maintain communications ;-)

How about a vertical suspended from a hunk of plastic pipe ? Try
letting it hang down from the balcony, as far out as you can safely
suspend it. I've gotten away with using a 24 guage wire suspended with
a collapsable/extendible fishing pole with reasonable results, compared
to trying to use a short dipole inside a hotel room....

Though far from optimum, sometimes almost anything is better than nothing.

2175. Why do Muslims think that Islam is true. Is there any factual basis?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-02-12 12:45:18 UTC
From: small giant <mutawafayez@yahoo.com>
Message-ID: <76939dda-98a3-47bf-8cc3-5ae2442725ee@l16g2000hsh.googlegroups.com>
Source record: 28147

Question:
There are many religions.

Why do Muslims think that Islam is true. Is there any factual basis?

Answer:
Praise be to Allah.

This is a reasonable enough question for one who has not entered Islam, but one who believes in and practices this religion already knows the blessings which are his because of this religion. There are many reasons for this, which include the following:

(1) The Muslim worships One God, Who has no partner, and Who has the most beautiful names and the highest attributes. Thus the Muslim's focus and aim is concentrated, focused on His Lord and Creator; he puts his trust in Him and asks Him for help, patience and support; he believes that Allaah is able to do all things, and has no need of a wife or son. Allaah created the heavens and earth; He is the One Who gives life and death; He is the Creator and Sustainer from Whom the slave seeks provision. He is the All-Hearing Who responds to the supplication of His slave, and from Whom the slave hopes for a response. He is the All-Merciful and All-Forgiving, to Whom the slave turns in repentance when he has committed a sin or fallen short in his worship of Allaah. He is the Omniscient and All-Seeing, who knows all intentions and what is hidden in people's hearts. The slave feels ashamed to commit a sin by doing wrong to himself or to others, because his Lord is watching over him and sees all that he does. He knows that Allaah is All-Wise, the Seer of the Unseen, so he trusts that what Allaah decrees for him is good; he knows that Allaah will never be unjust to him, and that everything that Allaah decrees for him is good, even if he does not understand the wisdom behind it.

(2) The effects of Islaamic worship on the soul of the Muslim include the following:
Prayer keeps the slave in contact with his Lord; if he enters it in a spirit of humiliation and concentration, he will feel tranquil and secure, because he is seeking a "powerful support," which is Allaah, may He be glorified and exalted. For this reason, the Prophet of Islaam, Muhammad (peace and blessings of Allaah be upon him) used to say: "Let us find relaxation and joy in prayer." If something distressed him, he would hasten to pray. Everyone who finds himself faced with disaster and tries prayer finds strength, patience and consolation, because he is reciting the words of his Lord, which cannot be compared to the effect of the words of a created being. If the words of some psychologists can offer a little comfort, what do

you think of the words of the One Who created the psychologist?

Now let us look at zakaat, which is one of the pillars of Islaam. Zakaat purifies the soul from stinginess and miserliness, and accustoms people to being generous and helping the poor and needy. It will bring a great reward on the Day of Resurrection, just like other forms of worship. It is not burdensome, like man-made taxes; it is only 25 in every thousand, which the sincere Muslim pays willingly and does not try to evade or wait until someone chases him for it.

Fasting involves refraining from food and sex. It is a form of worship, and a way in which one can feel the hunger of those who are deprived. It is also a reminder of the blessings of the Creator, and it brings rewards beyond measure.

Hajj is the Pilgrimage to the sacred House of Allaah, which was built by Ibraaheem (Abraham, upon whom be peace). By performing Hajj one is obeying the command of Allaah and the call to come and meet Muslims from all over the world.

(3) Islaam commands all kinds of good and forbids all kinds of evil. It encourages good manners and proper treatment of others. It enjoins good characteristics such as truthfulness, patience, deliberation, kindness, humility, modesty, keeping promises, dignity, mercy, justice, courage, patience, friendliness, contentment, chastity, good treatment, tolerance, trustworthiness, gratitude for favours, and self-control in times of anger. Islaam commands the Muslim to fulfil his duty towards his parents and to uphold family ties, to help the needy, to treat neighbours well, to protect and safeguard the wealth of the orphan, to be gentle with the young and show respect to the old, to be kind to servants and animals, to remove harmful things from the road, to speak kind words, to forgive at the time when one has the opportunity to take revenge, to be sincere towards one's fellow-Muslims, to meet the needs of the Muslims, to give the debtor time to repay his debt, to prefer others over oneself, to console others, to greet people with a smiling face, to visit the sick, to support the one who is oppressed, to give gifts to friends, to honour his guest, to treat his wife kindly and spend on her and her children, to spread the greeting of peace (salaam) and to seek permission before entering another person's house, lest one see something private that the other person does not want one to see.

Some non-Muslims may do these things out of politeness or good manners, but they are not seeking reward from Allaah or salvation of the Day of Judgement.

If we look at what Islam has prohibited, we will find that it is in the interests of both the individual and society as a whole. All these prohibitions serve to safeguard the relationship between the slave and his Lord, and the relationship of the individual with himself and with his fellow-man. The following examples demonstrate this:

Islam forbids the association of anything in worship with Allaah and the worship of anything other than Allaah, because this spells doom and misery. Islaam also forbids visiting or believing soothsayers and fortune-tellers; magic or witchcraft that may cause a rift between two people or bring them together; belief in the influence of the stars on events and people's lives; cursing time, because Allaah is directing its affairs; and superstition, because this is pessimism.

Islam forbids cancelling out good deeds by showing off, boasting or reminding others of one's favours; bowing or prostrating to anything other than Allaah; sitting with hypocrites or immoral people for the purposes of enjoying their company or keeping them company; and invoking the curse or wrath of Allaah on one another or damning one another to Hell.

Islaam forbids urinating into stagnant water; defecating on the side of the road or in places where people seek shade or where they draw water; from facing the qiblah (direction of prayer) or turning one's back towards it when passing water or stools; holding one's penis in one's right hand when passing water; giving the greeting of salaam (peace) to one who is answering the call of nature; and putting one's hand into any vessel before washing it, when one has just woken up.

Islaam forbids the offering of any nafl (supererogatory) prayers when the sun is rising, when it is at its zenith, and when it is setting, because it rises and sets between the horns of Shaytaan (Satan); praying when there is food prepared that a person desires; praying when one urgently needs to pass water, stools or wind, because that will distract a person from concentrating properly on his prayer.

Islam forbids the Muslim to raise his voice in prayer, lest it disturb other believers; to continue offering supererogatory prayers at night when one feels drowsy - such a person should sleep then get up; to stay up all night in prayer, especially one night after another; and to stop praying when there is doubt as to the validity of one's wudoo' - unless one hears a sound or smells an odour.

Islaam forbids buying, selling and making "lost and found" announcements in the mosque - because it is the place of worship and remembrance of Allaah, where worldly affairs have no place.

Islam forbids haste in walking when the iqaamah (call immediately preceding congregational prayer) is given, and prescribes walking in a calm and dignified manner. It is also forbidden to boast about the cost of building a mosque; to decorate a mosque with red or yellow paint or adornments which will distract the worshippers; to fast day after day without a break; and for a woman to observe a supererogatory fast when her husband is present without his permission.

Islaam forbids building over graves, making them high, sitting on them, walking between them wearing shoes, putting lights over them or writing on them. It is forbidden to disinter the dead or to take graves as places of worship. Islam forbids wailing, tearing one's

clothes or leaving one's hair unkempt when a person dies. Eulogizing the dead in the manner of the times of Ignorance (Jaahiliyyah) is also forbidden, although there is nothing wrong with informing others that a person has died.

Islaam forbids the consumption of riba (interest); all kinds of selling which involve ignorance (of the product), misleading and cheating; selling blood, wine, pork, idols and everything that Allaah has forbidden - their price, whether bought or sold - is haraam; najash, which is offering a price for something one has no intention of buying, as happens in many auctions; concealing a product's faults at the time of selling; selling something which one does not own or before it comes into one's possession; undercutting, outbidding or out bargaining another; selling produce before it is clear that it is in good condition and free of blemish; cheating in weights and measures; and hoarding. A partner who has shares in a plot of land or a date palm tree is forbidden to sell his share without consulting his partners. It is forbidden to consume the wealth of orphans unjustly; to bet or gamble; to take anything by force; to accept or offer bribes; to steal people's wealth or to consume it unjustly; to take something for the purpose of destroying it; to undermine the value of people's possessions; to keep lost property which one has found, or to keep quiet about it and not announce it, for it belongs to the one who recognizes it; to cheat in any way; to ask for a loan with no intention of repaying it; to take anything of the wealth of a fellow-Muslim, unless it is given freely, because what is taken because of another person's shyness is haraam; and to accept a gift because of intercession.

Celibacy and castration are forbidden, as is marrying two sisters, or a woman and her aunt (paternal or maternal), whether he marries the aunt after marrying her niece or vice versa, for fear of breaking the ties of kinship. It is forbidden to make deals in marriage, such as saying "Let me marry your daughter and I will give you my daughter or sister in marriage." Such reciprocal deals are a form of oppression and injustice, and haraam. Islaam forbids mut'ah (temporary marriage), which is a marriage contract for a period of time agreed by the two parties, at the end of which the marriage expires. Islaam forbids intercourse with a menstruating woman, until she has purified herself (by taking a bath after her period ends), and also forbids anal intercourse. A man is forbidden to propose marriage to a woman when another man has already proposed to her, unless the other man withdraws his proposal or gives him permission. It is forbidden to marry a previously-married woman without consulting her, or a virgin without seeking her permission. It is forbidden to wish (a newly married couple) "Bi'l-rafaa' wa'l-baneen (a joyful life and many sons)," because this is the greeting of the people of Jaahiliyyah, who hated daughters. The divorced woman is forbidden to conceal what Allaah has created in her womb (if she is pregnant). A husband and wife are forbidden to speak (to others) about the intimacies of married life. It is forbidden to turn a woman against her husband or

to take divorce lightly. It is forbidden for a woman to ask for another's divorce, such as asking a man to divorce a woman so that she can marry him. A wife is forbidden to spend her husband's money without his permission, or to keep away from his bed without good reason, because the angels will curse her if she does that. A man is forbidden to marry his father's wife, or to have intercourse with a woman who is pregnant from another man. It is forbidden for a man to practise 'azl (coitus interruptus) with his free wife without her permission. It is forbidden for a man to return home from a journey late at night and startle his family, unless he has previously notified them when he will arrive home. A man is forbidden to take anything of his wife's mahr (dowry) without her consent, or to keep annoying his wife so that she will give up her wealth.

Islaam forbids women to make a wanton display of themselves (tabarruj). It also forbids extreme forms of female circumcision. Women are forbidden to admit anyone into their husband's home without his permission; his general permission is acceptable so long as they stay within the limits of sharee'ah. It is forbidden to separate a mother and child (in case of divorce); to let one's womenfolk behave foolishly (in an immoral fashion) and not say anything; to let one's gaze wander everywhere; and to follow an accidental glance with an intentional glance.

Islaam forbids the eating of dead meat, regardless of whether it died by drowning, strangulation, shock or falling from a high place; eating blood, pork and anything slaughtered in a name other than that of Allaah or for idols; eating the flesh or drinking the milk of beasts that feed on filth and waste matter; eating the flesh of every carnivorous beast that has fangs and every bird that has talons; eating the meat of domesticated donkeys; killing animals by keeping them and throwing stones at them until they die, or detaining them without food until they die; slaughtering with teeth or nails; slaughtering one animal (for food) in front of another; or sharpening the knife in front of the animal to be slaughtered.

In the area of clothing and adornment, men are forbidden the extravagance of wearing gold. Muslim are forbidden to be naked or to expose their thighs; to leave their clothes long (below the ankles) and trail them on the ground for the purpose of showing off; and to wear clothes that will attract attention.

It is forbidden to bear false witness; to make false accusations against a chaste believing woman; to accuse someone who is innocent; to utter lies; to slander and backbite; to call people by offensive nicknames; to spread gossip and malicious slander; to make fun of the Muslims; to boast about one's status; to shed doubts on a person's lineage; to utter slander, insults and obscenities; to speak in an indecent or rude manner; or to utter evil in public, except by one who has been wronged.

Islaam forbids telling lies; one of the worst kinds of lie is to lie about dreams, like fabricating dreams and visions in order to prove one's virtue, or make some material gains, or to frighten an enemy.

Muslims are forbidden to praise themselves, or to talk in a secret way: two may not converse secretly to the exclusion of a third, because this is offensive. It is forbidden to curse a believer or someone who does not deserve to be cursed.

Islaam forbids speaking ill of the dead; praying for death; wishing for death because of some suffering that one is passing through; praying against one's self, one's children, one's servants or one's wealth.

Muslims are told not to eat the food that is directly in front of others or to eat from the centre of the dish or platter; rather they should eat from what is directly in front of them or thereabouts, because the barakah (blessing) comes in the middle of the food. It is forbidden to drink from a broken edge of a vessel, because this could cause harm; or to drink from the mouth of a vessel; or to breathe into it. It is forbidden to eat while lying on one's stomach; to sit at a table where wine is being drunk; to leave a fire burning in one's house when one sleeps; to sleep with Ghamr in one's hand, like an offensive smell or the remainder of food (grease); to sleep on one's stomach; or to talk about or try to interpret bad dreams, because these are tricks of the Shaytaan.

It is forbidden to kill another person except in cases where it is right to do so; to kill one's children for fear of poverty; to commit suicide; to commit fornication, adultery or sodomy (homosexuality); to drink wine, or even to prepare it, carry it from one place to another, or sell it. Muslims are forbidden to please people by angering Allaah; to offend their parents or even to say "Uff" (the slightest word of contempt) to them; to claim that a child belongs to anyone but his real father; to torture by means of fire; to burn anyone, alive or dead, with fire; to mutilate the bodies of the slain; to help anyone commit falsehood; or to cooperate in wrongdoing and sin.

It is forbidden to obey any person by disobeying Allaah; to swear falsely; to swear a disastrous oath; to eavesdrop on people without their permission; to invade people's privacy or look at their private parts; to claim something that does not belong to one or that one did not do, for the purpose of showing off; to look into someone's else's house without permission; to be extravagant; to swear an oath to do something wrong; to spy on others or be suspicious about righteous men and women; to envy, hate or shun one another; to persist in falsehood; to be arrogant or feel superior; to be filled with self-admiration; to be pleased with one's arrogance. Islam forbids taking back one's charity, even if one pays to get it back; employing someone to do a job without paying him his wages; being unfair in giving gifts to one's children; bequeathing everything in one's will and leaving one's heirs poor - in such a case the will should not be executed; writing a will that concerns more than one third of one's legacy; being a bad

neighbour; or changing a will to the detriment of one or some of one's heirs. A Muslim is forbidden to forsake or shun his brother for more than three days, except for a reason sanctioned by sharee'ah; to hold small stones between two fingers and throw them because this could cause injury to eyes or teeth; to include his heirs in a will, because Allaah has already given heirs their rights of inheritance; to disturb his neighbour; to point a weapon at his Muslim brother; to hand someone an unsheathed sword, lest it harm him; to come (walk) between two people except with their permission; to return a gift, unless there is some shar'i objection to it; to be extravagant; to give money to foolish people; to wish to be like someone to whom Allaah has given more of something; to cancel out his charity by giving offensive reminders of his giving; to wilfully conceal testimony; or to oppress orphans or scold one who asks for help or money. It is forbidden to treat with evil medicines, because Allaah would not create a cure for this ummah which includes something that He has forbidden. It is forbidden to kill women and children in warfare; to boast to one another; or to break promises.

Islaam forbids betraying a trust; asking for charity that one does not need; alarming a Muslim brother or taking away his possessions, whether jokingly or seriously; changing one's mind after giving a gift, except in the case of a gift from a father to his child; practising medicine without experience; or killing ants, bees and hoopoe birds. A man is forbidden to look at the 'awrah (private parts) of another man, and a woman is forbidden to look at the 'awrah of another woman. It is forbidden to sit between two people without their permission; or to greet only those whom one knows, because the greeting is to be given to those whom you know and those whom you do not know. A Muslim is forbidden to let an oath come between him and good deeds; he should do what is good and make expiation for the oath. It is forbidden to judge between two disputing parties when one is angry, or to judge in favour of one party without hearing what the other has to say. It is forbidden for a man to walk through the market-place carrying something - like a sharp weapon - that could harm the Muslims, unless it is properly covered. A Muslim is forbidden to make another person get up, so that he can take his place.

There are more commands and prohibitions which came for the benefit and happiness of individuals and mankind as a whole. Have you ever seen any other religion that can compare to this religion?

Read this response again, then ask yourself: is it not a great pity that I am not one of them? Allaah says in the Qur'aan (interpretation of the meaning): "And whoever seeks a religion other than Islam, it will never be accepted of him, and in the Hereafter he will be one of the losers." [Aal 'Imraan 3:85]

Finally, I hope that everyone who reads this will be guided to the correct way and to follow the truth. May Allaah protect you and us from all evil.

Can someone explain how these two relate in a waveguide.
My limited understanding is, group velocity is slow near cutoff and
increases as frequency increases to almost c.
I don't know the difference between group velocity and phase velocity.
Thanks, Mike

Phase velocity is the velocity of a constant phase point. For example, if you look at a point where the voltage or current wave crosses zero going in the positive voltage or current direction, it moves down the waveguide at the phase velocity. In a waveguide, the phase velocity is always greater than the speed of light c. It approaches c at very high frequency, and increases without bound as cutoff is approached.

The group velocity is the speed at which information can be moved. In other words, a change in the signal (e.g., turning it on or off or changing its amplitude) propagates at the group velocity. In a waveguide, the group velocity approaches c at very high frequency and 0 at cutoff.

Mathematically, vp = c/sqrt(1 - (f/fc)^2)
vg = c * sqrt(1 - (f/fc)^2)

where vp is the phase velocity, vg is the group velocity, f is the frequency, and fc is the cutoff frequency. These equations are valid for TE and TM modes in hollow waveguides.

A medium in which the phase velocity varies with frequency is called a dispersive medium, and all hollow waveguides are in this category. Phase and group velocities are the same in non-dispersive media such as coaxial cable.

Kraus uses a caterpillar as an example: The humps on the caterpillar's back move at the phase velocity, but the caterpillar moves at the group velocity.

Hate to tell you this, but there is no 'factual' evidence for any
religion. It's a matter of 'faith', which requires no 'factual'
evidence. Want to be Muslim? Good for you, do so. Please keep your
'converting' where it belongs. I don't need it. Thank you.

Try the Half Sloper if you could.
It is quarter wave wire suspended between balcony and run at about 45 deg
down to a tree or whatever. There is a good chance you will end up with 50
ohm impedance and can be fed directly with a coax, shield connected to metal
railing or door frame and center wire to the antenna. Trim to frequency.
Had one like that from the 9th floor at the hotel in Bahamas, worked very
well.

That's true for metal waveguides. Dielectric guides always have at
least one mode at all frequencies, and vp <= c.
>

This is true for narrowband modulation, because it assumes that
d(omega)/dk is constant. It also requires the approximation that the
pulse shape propagates unchanged, which means that it works only for
short distances. A very long guide with linear dispersion will produce
the Fourier transform of the input. Various grandstanding academics
have published papers claiming group velocities higher than c, but it
always turns out to violate one or other of these conditions.

Cheers,

Phil Hobbs

Group velocity wants to describe a pulse containing more than one photon
frequenccy.

In dispersive media the group velocity is a function of frequency of the
photons that form
a physical signal. So neighboured frequencies have a little different
velocities. That is what is behind.

So group velocity as one uses the terminus in hard physical theory is
nothing else as the true physical velocity at a certain frequency of the
photonic carrier resp. field.

Group velocities of wave packets is something apart from that. If you have a
carrier that containes
a spectrum of frequencies it describes the broadening of the signal due to
different carrier frequencies in
which have different velocities.
This definition is therefore unsharp and has only qualitative picturesque
meaning !

So group velocity in a sharp sense is just the real velocity which with the
field and the photons in move
at and only at a certain frequency.

So we should wrap the earth in a Dyson sphere to make sure none of
those evil ET's do us harm?

Yours and others phobia do make for great movies though.

Lets think about it.

Any "evil" ET's that were advanced enough to find and destroy us
wouldn't likely need to find our radio transmissions to find us. The
earth has plenty of cues that there is life here. And any aliens who
could physically come here would be able to find those clues.

Okay. Assuming that is 34 feet per leg, you might be cut a little long for 40 meters. (Let me make sure I'm correct here - this is a linear loaded dipole, yes?)

What would be good to know is the frequency where you are at your lowest SWR.

Can you beg borrow or steal an antenna analyzer? Your antenna is probably cut for somewhere outside of where you can transmit with your rig. That would be the quick way to find out. Otherwise you should take SWR measurements across the band to see if that gives you an idea about how the antenna is cut.

Another thing is to try a measurement without the capacity hat - see where that puts you. It might just get you a lot closer to tuned.

I was in a hurry this morning and didn't ask my main question.
I think at this point I understand different frequencies travel at different
speeds.
Group Velocity vs Velocity Factor what is the difference?
If vg = c * sqrt(1 - (f/fc)^2) hmm, maybe I should tell what I think I know.
(I'm way over my head on this subject).

If I generate a spark (many frequencies) all these frequencies combine to make a waveshape, as the wave travels down the waveguide the waveshape changes because different frequencies are traveling at different speeds? Correct me as needed.
So is 'group velocity' the velocity the peak of the signal as it travels down the waveguide?
Forgive my ignorance but the formula vg = c * sqrt(1 - (f/fc)^2) doesn't work for me. (1-(f/fc)^2) is negative and I can't get the sqrt of a negative. What did I miss?
Thanks, Mike

Thanks, Yuri. Unfortunately, there's no good tree or pole to attach
to
below. There *is* a parking garage about 400 feet straight across
from
me though! LOL, would be a really long wire.

I may try the dangling wire that Rick described earlier in this
thread.
I'll just have to figure out what fraction of 20m and 40m wavelengths
that will work best with that and cut the wire(s) accordingly. I have
about 50' of height to work with.

Or maybe a MFJ-1622 clamped to the railing?
http://www.eham.net/reviews/detail/2035

All,

Some textbooks use c with a subscript for propagation velocity. When we use c for propagation velocity we can talk about a "particle" accelerated to a velocity v such that

c_h2o < v < c_free_space

Closer to home, we can imagine a cosmic ray passing the shack with a velocity such that

c_RG58 < v < c_ladder_line

I suggest anyone wishing to clarify his or her posts apply subscripts to c to indicate how c is being used.

Thank you,

Steven, KD7YTE

All;

Years ago I looked a book about Einstein's famous equation E=MC2. I quickly closed it.

Steven's comments above, IMHO, pretty much cover the description of the value of c in various media in a manner that has greater clarity than my comments had.

there's a bit more to it than that.. and, there's a whole industry that
has sprung up to do wiring retrofits, adapters, inspect your house,
etc., as well as to litigate claims of one sort or another. Tough to
find unbiased information on the web.

It has to do with which alloy of aluminum was used, and the casual use
of the wrong alloy with connection methods not suitable for it (i.e.

screw terminals). When the copper prices rose and the economy sank in the late 60s early 70s, they used the same aluminum wire (EC1350?) as had been used (successfully) for overhead and underground feeders for decades. The wire companies will make wire out of any alloy you want, so folks said, give me that stuff I've been getting in 2/0, except in AWG14 or AWG12.

Bad choice, as it happens. An alloy that is good for big ol' fat feeders supporting their own weight on a 100 ft span, especially bare ones, going into big (aluminum) compression clamps, is probably not a good choice for electricians working in tight quarters, stripping insulation with a penknife, and then wrapping it around a screw made of steel that's installed into a threaded hole made of brass. Even worse, the quickwiring "push it in the hole" type connectors.

Another problem was the change from brass to steel screws in the terminations, also as a result of cost. The Coefficient of Thermal Expansion (CTE) mismatch between brass and aluminum isn't as big as between steel and aluminum. And, issues with Steel screws staying tight in brass threads, etc.

I don't know that cold flow is actually an issue. After all, most power lines and the feeder to your house is done with old style aluminum wires, into a compression screw termination, and failures are very rare, even with the connector untouched for 50 years. It's more the gradual loosening from temperature cycling, which is self aggravating: small gap opens, contact area reduces, localized heating causes more of a gap, etc.

Modern aluminum wiring uses another alloy (AA-8000 series or ACM), which has better mechanical properties: it's less brittle, so nicks and tight turns don't cause problems, it's also mechanically weaker, but that's not an issue, unlike with overhead power lines, which need to support their own weight. In addition, the termination device (the screws or clamps) are specifically designed to work with the aluminum (or copper) wire. Things like little ridges and grooves in the plate you tighten down against.

Some interesting photos at:
http://www.qpi-inspect.com/aluminum06-02-04.pdf

2194. practical yagi question

Newsgroup: rec.radio.amateur.antenna

Hi all,

it's time to build new antennas for V/UHF season. Until now I always used over the boom insulated elements mounting and in almost all cases folded dipoles with 4:1 coaxial balun/transformer. In one case I changed this driven element to a simple split dipole because the antenna didn't seem to work well (when in facts was my homebrew tx which wasn't working really well).
Now I read in some web pages that split dipoles work better for yagis (no balun loss, balun is narrowband, split dipole can be easily tuned...). This make enough sense to me (doesn't it?) so I'm willing to use this driven element on the new antennas.
Now the question for the experts:

is this driven element really "better"? How about braid currents?

In the future yagis I want to use insulated through the boom elements (they are really easier to manufacture for me this way). With folded dipole the element's plane will pass approximately on the center of the folded dipole gap, if however the driven element is a split dipole, this element will be mounted over the boom and insulated for mechanical and electrical reasons, thus the driven element will lay in a different plane than all the other elements. Is this acceptable?

Thanks in advance for all hints.

That antenna is based on one B&W used to market. I had the B&W version in a third floor apartment window back in the 80s, and it worked reasonably well. The vertical had a long counterpoise wire that I stretched out through the apartment -- I tuned the antenna by adjusting the length of the counterpoise. Worked fine, but be careful to not set the rug on fire :-)

>

If you threw a stone into a pond, the group velocity of the wave
generated would be how fast the ripples moved away from the point
where the stone hit the water, while the phase velocity would be how
long it took for a ripple peak to go from a peak to a trough and
then back to a peak.

Likening it to a pair of scissors closing while cutting through a
sheet of paper, the group velocity would be the speed of the ends of
the blades approaching each other, while the phase velocity would be
the speed of propagation of the cut as the blades sliced the paper
apart.

I can't speak for your specific situation, but here is how I handled
the similar situation.

I used either a multi-band-parallel dipole (sometimes referred to as a
fan dipole) or a 135 foot dipole fed with 300 ohm twin-lead. These
antennas were raised about 100 feet or so into trees by mason's line
which can be purchased at Walmart or most hardware or building supply
stores.

My first antenna was taken down by tree movement shortly after having
put it up. After that, I created a 'fuse' mechanism that released the
line if too much tension was placed on the antenna end.

What I did was to pull the antenna up partially until the antenna was
just above the ground. I wrapped the excess line around two nails I

used as a make-shift cleat. Then I wrapped the string around a nail and mounted it into the bark of the tree. I did this several times a different intervals until the antenna was raised to a maximum height still providing for general tree movement in the wind. When an excess wind strikes, it removes one or more of the nails lowering the antenna without breaking the string, or if a limb hit the wire, the antenna was low enough for me to reach the end of the line and put it back up.

disclaimer:

I didn't really trust the mason line to work as well as it did. I typically replaced it every six months or so (as I replaced antennas this often, mostly in experimentation or for improvements.)

While I still use it today, I don't recommend it for anyone wanting to put up a permanent antenna and just leave it alone for more than a year.

That would seem to be very unbalanced, even at 50 ohms. Could have lot's of
RF feedback but maybe it is not such a big problem at low power (QRP).
Better to connect the shield to the ground terminal in the supply mains
(thereshould be a functional safety ground in most hotels and it would be
better than a door frame or railing).

> Group Velocity vs Velocity Factor what is the difference?

Velocity factor is the ratio of the velocity of waves in the medium to the velocity of the speed of light in a vacuum. That is, VF = v/c, where v is the velocity in the medium, c is the speed of light in a vacuum, and VF is the velocity factor. I'm more familiar with its use in non-dispersive media, but there's no reason it couldn't also be used for dispersive media. If it is, then group velocity and phase velocity would each have a different velocity factor (and it would be greater than one for the phase velocity in a hollow waveguide), and it would also be a function of frequency.

> If vg = c * sqrt(1 - (f/fc)^2) hmm, maybe I should tell what I think I know.
> (I'm way over my head on this subject).

I made an error and reversed f and fc in the equations. I've posted a correction.

> If I generate a spark (many frequencies) all these frequencies combine to
> make a waveshape, as the wave travels down the waveguide the waveshape
> changes because different frequencies are traveling at different speeds?
> Correct me as needed.

Yes, that's correct. A dispersive medium distorts any waveshape except a pure sine wave. People used to working in the frequency domain often forget the vital importance of phase response in preserving waveshape integrity. I learned the hard way that microstrip line is dispersive when designing a delay line loss compensator for a high-speed sampling oscilloscope used for TDR, where very good waveshape integrity is essential.

> So is 'group velocity' the velocity the peak of the signal as it travels
> down the waveguide?

Assuming that by "signal" you mean something other than a sine wave, it becomes a matter of definition depending on the application. When dealing with step functions, for example, the 50% point on the step is commonly used.

> Forgive my ignorance but the formula vg = c * sqrt(1 - (f/fc)^2) doesn't

I don't think it works equally well for all kinds of trees. For many years I've used nylon twine or mason's line for raising Field Day antennas. The trees here in the Pacific Northwest are of course mostly evergreens which have a lot of pitchy sap and in many varieties, fairly soft wood. An antenna with a fair amount of tension causes the line to dig into the wood in a very short period of time. And even after two days, the line can sometimes be hard to get down because of being seized in the pitchy slot it cuts in the wood. So while it's fine for a very short time temporary setup, I don't consider it viable for longer term installation in the kinds of trees we have here.

It should help, but I honestly can't say how much. The tape should help keep moisture out, anyway.

Surely the larger the surface area of the contact, the longer before it fails to make contact somewhere. There's no reason not to use it, but be on the lookout for intermod and harmonics or noise in the receiver when the wind blows and jiggles it, and don't be surprised when it fails.

Mouser (http://www.mouser.com/) and Allied (http://www.alliedelec.com/) also stock Caddock. If you need only one or two, you won't get stung $5 for a less-than $25 order. Their prices are only a tad higher.

For higher power capability, you can go with series-parallel combinations of such devices (on a heatsink). For even higher power, there are devices up to ~800W in a flange-mount. The RF Cafe (http://www.rfcafe.com/) has a list of vendors.

The easiest way to export SWR sweep data is via the LastZ.txt file,
described in the EZNEC manual. The impedance data can be converted into
S or other parametric forms with a spreadsheet or simple program.

Yes, and at that time, before they allegedly engineered the DNA of homo erectus to homo sapiens sapiens, none of the human ancestors were sending out radio waves and yet we still were discovered by the Annunaki leader(s) Elohim. Thus, Richard's concern of advanced civilizations discovering our crude radio wave transmissions could come to fruition with or without controls on radio emissions ;-)

Roy, thanks a million. I've already followed your advice and it worked beautifully. In fact, I didn't have to make any conversion at all because I used the impedance data in Last.txt as Z-parameters directly, which my program could make use of.

Thanks again,

Al W6LX

well, I made two quagi one year, they worked well. The problem is that
you don't easily find good design procedures for quagi (neither for
quads).

Ok, guys you helped me get a better understanding without the math, that I
wouldn't
be able to do.
The end point of this information is to initiate a spark pulse at one end
of a
waveguide and pickup the pulse two times. So I'll have two pickups separated
by distance.
The time between the two received pulses is distance times the velocity of
the waveform.
Hence all my questions about vf, vg and vp.
Any added thoughts are appreciated.
Thanks, Mike
p.s. I have someone that can do all the maths, I just want a better
understanding
of what's happening.

Francesco,
The 'best' driven element is one that is the easiest and most
practical for you to make/use. I'm sure that someone has done testing
of this sort, and I also think that there isn't all that much
difference in performance (all things considered). Lots of variables
in that "best" qualification!

I could fashion a 24 gauge 1/2-wavelength 20m dipole, which I know
about its footprint when strung horizontally at 1/2-wavelength above
the ground, but is it of any use stood on end (as in dangled from
my balcony and tapped in the center)?

Thanks,
~swooz

about its footprint when strung horizontally at 1/2-wavelength above
the ground, but is it of any use stood on end (as in dangled from
my balcony and tapped in the center)?

Thanks,
~swooz

Sure is -- tis a vertical dipole - works well at low heights where a horizontal dipole should be elevated above ground - half wavelength +

Be sure to center tap it for proper impedance match. Not end fed.

Feedline should be 90 deg from the dipole or as near as you can get it.

I use a vertical dipole on six meters - works well

Lamont

When I was first licenced I lived in a 2 story apartment. For 20 - 10 meters I hung Clothes line pulleys at the end of both bedrooms (abotu 25 feet) and small diameter rope tween the pulleys. I then attached the GROUND side of the dipole and pulled it across letting the Center dangle down. Inverted L ..... and I worked 100+ countries and WAS on that little piece of wire. I used small copper wire, never ran more than 100W and it was near invisible even in daytime.

I have seen that at Nimtz too. He modifies the dispersion relation. Since i
have not seen that before
i just can say that light having this dispersion relation does not obey the
wave equation but a more general equation which is called Klein - Gordon
equation. So it is not elliptic polarized light.
Such light can also move in homogene waves but with velocities less than c
and be frozen at f =fc.
For f >fc you get inhomogene waves and those can tunnel almost instant.
Thats proof too.

But whats fc ? I dint know.

So i am going after that, my trial to find out something is that it light
where the ellipse of elliptic polrized light
rotates or in other words the field takes a screw. But ok i am not shure
about that last now.

Josef

2225. High ohm connections

I'm working QRP (5W max) and I'm construction my own antennas. I've read that antenna efficiency can be degraded by "high ohmic connections" (especially deleterious to QRP ops). I'm assuming that we shouldn't make potato-sized solder joints when assembling the antenna. So, I was wondering what would be the best way to connect various parts of the antenna?

Example: I've created a 4:1 balun based on Ron's (VK2DQ) description in his article "Understanding and building the OCF dipole." The toroid windings had to be connected. So, rather than twist them together (they are 18 AWG) and solder them, I laid the pieces side-by-side (abt 1/4") and solder them together. Is that a "high ohmic" connection? If so, what other way could the pieces be soldered together w/o creating a high ohmic connection?

For other parts of the antenna (e.g., the feed-point) would connectors (quick release, ring type, etc.) be better than a solder joint?

Thanks,

Well, I recently finished installation of a 160 meter lazy quad,
horizontal loop, fed with home made 600 ohm feed line. All connections
have crimp type terminals that are also soldered. The plastic was
removed from the terminal before use. Then the terminals are bolted
together. I change things quite often and needed to have an easy to
disconnect the feed line from the antenna and house. Seems to be
working just fine.

Any soldered connection is fine, and not a "high ohmic connection". The only time you really need to worry is if you're using an electrically small antenna such as a small loop for transmitting and even then any soldered joint is ok.

I often use wire nuts (the sort used for house wiring) for temporary or even semi-permanent antenna connections.

2228. Standing wave and power

Newsgroup: rec.radio.amateur.antenna
Date: 2008-02-14 00:16:17 UTC
From: Yuri Blanarovich <K3BU@optonline.net>
Message-ID: <47b3885e$0$25023$607ed4bc@cv.net>
Source record: 28250

From Kraus: Antennas

" 1-1. Definitions. A radio antenna may be defined as the structure associated with the region of transition between a guided wave and a freespace wave, or vice versa.
In connection with this definition it is also useful to consider what is meant by transmission line and by resonator. A transmission line is a device for transmitting or guiding radio-frequency energy from one point to another. Usually it is desirable to transmit the energy with a minimum of attenuation, heat and radiation losses being as small as possible. This means that while the energy is being conveyed from one point to another it is confined within the transmission line or to the vicinity of the line. Thus, the wave transmitted along the line is one-dimensional in that it does not spread out into space but follows along the line. From this general point of view the term transmission line includes not only coaxial and two-wire transmission lines but also hollow pipes, or wave guides.
A generator connected to an infinite, lossless transmission line produces a uniform traveling wave along the line. If the line is short-circuited, a standing wave appears because of interference between the incident and reflected waves. A standing wave has associated with it local concentrations of energy. If the reflected wave is equal to the incident wave, we have a pure standing wave. The energy concentrations in such a wave oscillate from entirely electric to entirely magnetic energy and back twice per cycle. Such energy behavior is characteristic of a resonant circuit, or resonator. Although the term resonator, in its most general sense, may be applied to any device with standing waves, the term is usually reserved for devices with stored energy concentrations that are large compared with the inflow or outflow of energy.(2)

(2) The ratio of the energy stored to that lost per cycle is proportional to the Q, or sharpness of resonance of the resonator."

From Wikipedia:

"In physics, power (symbol: P) is the rate at which work is performed or energy is transmitted, or the amount of energy required or expended for a given unit of time.
When the rate of energy transfer or work is constant, all of this can be simplified to

P=W/t=E/t

where W and E are, respectively, the work done or energy transferred in time t (usually measured in seconds)."

Yuri and W9UCW also found that
on a quarter wave resonant vertical antenna, which is a standing wave circuit, and demonstrates that at the current maximum at the base, or at the bottom of the loading coil, the current heats the wire. At the tip, where there is a voltage maximum, the corona or neon bulb lights up. Both effects demonstrating that there is power (energy over time) being exhibited. Kraus so effectively explains it in the introduction to his book, but the "expertise" on this news group insists on otherwise - "no power in standing wave circuit".

Since you are drawing power, by lighting a neon bulb, or by creating a corona, or by heating a wire through current flow, it cannot be a standing wave in the theoretical sense. It is possible to use perfect or ideal components in a theoretical analysis, but real life tends to throw a spanner in the works. In any real standing wave circuit there are power losses due to radiation or resistance. The nearest one could come to the idealised standing wave circuit is the current flow around a superconductor. The current flows continuously until an outside influence such as a magnetic field interrupts the flow. Depending on the circumstances, a physical (magnetic) repulsive force may be generated or a feedback loop may develop resulting in rapid temperature rise, loss of superconductive properties and a rather loud bang as the circuit comes apart. Clearly power does flow in all real life standing wave circuits.

The energy in the traveling waves was supplied as power
by the source during the power-on transient state and is
exactly the amount of energy needed to support the forward
and reflected waves. The energy in the forward and reflected
waves is dissipated during the power-down transient state.

Assuming an integer number of cycles per second, a one second
long lossless transmission line with a forward power of 200
watts and a reflected power of 100 watts contains 300 joules
of energy.

Daddy always said the solder joint oughta be mechanically sound before you even put the heat to it.
Use an abrasive and clean the wires to be joined.
Join them mechanically (like a good twist or compression connector) (If the wire is copper, this would be low-resistance in itself) - then flux it and solder it. (use Rosin flux - not acid flux).
Then considering its for an outside antenna, dip it in 3M ScotchKote which is like an electrical-grade varnish.
That would make a "low-ohmic" (some call it "low-resistance") connection.

Oh and considering you're only using 5 watts, you need to shake the antenna real hard while transmitting to be sure to get every little bit of RF out of it. :-)

Oh dear we are getting of the thread aren't we! So here goes. Anyone
read Robert Graves book "The White goddess"? Ther he makes a fairly
strong case that the religion of Genisis actually had 3 deities
1 God and 2 Goddesses. He get a lot of this idea from of all place's
Solomons temple and its construction. So maybe they wern't Aliens after
all just good old Polytheism.
In any event why hold up a sign saying "exploitable planet with
intelligent? race here" maybe they are a bit lazy just like us.

My present antenna, which is for 160m and above, is about the size of
two shoe
boxes and is less than 2:1 swr (50 ohm) across the band when
situatedat the
top of my tower.
I have googled a lot over the last month or so to determine if there
has been
claims for the 'smallest' transmitting antenna and what the criteria
consisted of.
If I knew what it was I would concentrate on making my antenna smaller
to reflect
something more close to point radiation which has been theorized as
being possible.
Seems like that there is no real definition of what a 'small' compact
antenna
actually comprises of together with power handling capabilities!
True, for receiving only there are many contestants all with
different criteria,
but for the ham community there is absolutely nothing for anybody to
compare
with other than such claims as 'mine is the smallest and I work
anything I can
hear' !. Can anybody point to a transmitting antenna that can be
considered
'small ' without the need for a ground plane, which thus puts it
into the
'antenna systems' class ?
For a point of interest, I am presently using a reflector made from a
garbage can lid,
but it is not acting in anyway a dish antenna works when the reflector
is grounded!
As an aside, most posters to the group are aware that a modest sum was
offered
who could disprove my claim but with no takers. So can we put that
particular subject
aside and concentrate only on the request of this posting which
should cut off
most of the insults ?
Best regards to all
Art Unwin

Hi Art,
Get a copy of Balanis' _Antenna Theory, Analysis and Design_,

second edition, and read section 11.5, Fundamental Limits of Electrically Small Antennas. Also, in the _Antenna Engineering Handbook_, third edition, read section 6, Small Antennas by Harold A. Wheeler. I won't vouch for any of the information, but it should give you some ideas on what the practical limits of small antennas are supposed to be by reputable people who have thought the subject through.
73,
Tom Donaly, KA6RUH

<SNIP>

Thanks to everyone who gave advice; very helpful.

The person who stated that "high ohmic connections" were deleterious to
QRP ops was describing his construction of a linear loaded dipole and
the connections to the inductance section of the antenna (see N5ESE's
article on the "Notebook antenna"
http://www.io.com/~n5fc/notebk_ant.htm). This is a small radiation
resistance antenna and could be affected by bad connections.

The balun's connections, described in my original post, will not be
subject to mechanical stress 'cuz it will be bolted down inside a
connection box and protected from the wx.

Thanks & 73

2236. Vertical Antenna Performance Question

Newsgroup: rec.radio.amateur.antenna
Date: 2008-02-14 04:58:31 UTC
From: N0GW <wescom@wildblue.net>
Message-ID: <47b7b286-28d1-44e4-8a28-263e3358d2aa@m34g2000hsb.googlegroups.com>
Source record: 28058

OK, I apparently drifted off the beaten path plus I seem to be experiencing some serious brain fade.

What I was doing was preparing a short presentation for new hams on the subject of vertical antennas. I was using EZNEC to produce some antenna pattern graphics. It was then that I noticed that when I overlayed the pattern from a vertical half wavelength dipole with that of a horizontal half wave dipole at the same center height over real ground that the pattern from the vertical was completely enclosed by the horizontal dipole pattern, at least broadside to the horizontal dipole that is. The vertical dipole pattern definitely showed a lower angle of peak radiation but no greater gain a low angles than the horizontal dipole.

At first, seeing the vertical dipole gain the same as the horizontal dipole, even at low elevation angles, was a little confusing but I had just scanned a bit of text on vertical antenna operation including calculation for reflected waves and stuff like the pseudo Brewster angle.

But then... I remembered talking to a couple guys in Germany on 75 meters the previous evening. From my location here in Missouri, I was hearing their signals on my 75 meter inverted L much stronger at 10 to 20 over S9 than on my dipole at S4 to S5. They noted the same difference in performance between the two antennas. As both the Dipole height and the top of the inverted L were at 50 feet, I thought this was a reasonable comparison. Also, the dipole is in the clear, resonant, and has been performing as well or better than other horizontal dipoles used by other hams in this area.

Furthermore, my experience switching between horizontal and vertical antennas on 75 meters matched that of other guys with both. I was starting to wonder why the mismatch between the theory I was familiar with and my experiences.

Jumping back in to the text books and spending some time 'googling' for more info I found nothing to conflict with the material I had previously covered. That was disconcerting. About the only glimmer of a solution to the question popped up when I looked at papers on ground or surface wave propagation. There were some vague comments about diffraction that seemed to indicate one of the loss factors involved with ground wave propagation is that some of the signal does not get diffracted low enough to keep in from being 'lost' to sky wave radiation.

As I continued chasing that thought, I found that discussions of sky wave propagation ignored ground wave and discussions of ground wave propagation considered sky wave as lost RF.

Now, after all that windup, what am I missing? I acknowledge ahead of time that I may be a dummy so don't bother explaining that to me. Why do reasonable size vertical antennas with proper radial systems under them outperform horizontal dipoles for DX operation for typical ham antenna support structure heights of 50 feet or so?

The interesting question then: Is the improved performance of vertical antennas over horizontal dipoles on 75 meters at DX distances due to a combination of direct radiation plus radiation from the ground in the area of strong ground wave strength out hundreds of meters? Is the ground wave leakage providing additional low signal strength in both transmit and receive?

Gary - N0GW

Understood Tom. Wheeler looks at the subject from many angles but
does
not get into overall specifics. For instance, the smallest volume
antenna can be based on wire size which in turn is based on power
output.
This effectively states that the smallest radiater is the size of a
pinhead!
Practicality states that the wire diameter is exceedingly small
diameter
plus extremely low power, all of which is based on a arrangement that
is
resonant. In practical terms I would point to a Fractal antenna
however, the
criteria for 'smallness' or 'compact' must factor in efficiency with
respect
to wave length where the latter antenna would fail. Same goes for the
EH
antenna which only can be regarded as a 'system'. Or for that matter
a
resister which as a load is just a heat exchanger.
In the amateur field one should incorporate max power allowed on key
down for a certain period of time without loading of any sort and
where
radiation is rated with respect to a unit volume. With that in mind I
have found nothing to aim for to qualify as a 'small' or 'compact'
antenna.
Looking at the trade magazine 'Antenna' there is always demands for a
"smaller"
design antenna as something that is holding up electronic progress,
but at
the same time zero reference as to what defines 'small' since design
is
covered by Maxwell and not by Congress
Best regards
Art Unwin.

> . . .

Yes, it does have a low radiation resistance:

21 MHz: 31.7 ohms
14 MHz: 11.6 ohms
7 MHz: 2.6 ohms
3.5 MHz: 0.64 ohms
1.8 MHz: 0.17 ohms

And the tuner has a lot of reactance to take care of, from about 180 ohms at 21 MHz to nearly 8000 at 1.8 MHz. If a 1.8 MHz tuner had a coil with Q = 400, the tuner loss alone would be 20 dB.

My model doesn't show the claimed spectacular rise in radiation resistance from the meander lines. Replacing them with straight 14 inch wires just about halves the radiation resistance. That's nearly 3 dB at the lower frequencies, so nothing to sniff at, but nowhere near the factor of up to 14 claimed. The meander lines cut the reactance by a factor of 1-1/2 to 2, which helps the tuner efficiency.

The fact that QSOs can be made with this antenna and QRP is yet another illustration of just how little radiated power is needed in order to communicate.

Take two bare copper wires (don't clean them), twist together and leave
in the weather for a few weeks. If you get any sort of rain and some
decent sun, before long you will have a "high ohmic" connection. The
more oxidation between the two wires at the point of contact, the higher
the resistance. This can be detrimental, especially if you're using low
power (QRP). On the other hand, if you have an amplifier and transmit
through this sort of poor connection it can actually get worse, and you
can end up with variable swr, which most amplifiers don't like....

Typically, any clean, tight joint will be fine for awhile, longer if
protected, and longer yet if soldered before you protect it.....

What you need to do is keep air and moisture from between the wires, once you've put them together with enough pressure to break through the surface oxide and make good metal-metal contact. That's how wire nuts and clamp and crimp type connections remain reliable for a long time. Of course, soldering accomplishes this too.

Hi Gary,

You have so much left unsaid, that it is shooting in the dark.
However, proceeding with that risk in mind....

A vertical dipole described above is not the vertical antenna that you
describe following:
>The interesting question then: Is the improved performance of
>vertical antennas over horizontal dipoles on 75 meters at DX distances
>due to a combination of direct radiation plus radiation from the
>ground in the area of strong ground wave strength out hundreds of
>meters? Is the ground wave leakage providing additional low signal
>strength in both transmit and receive?

Better? You are relying too heavily on anecdotal reports.

For one, I seriously doubt you compared a 75M vertical dipole to a 75M
horizontal dipole in your lecture - no one in your audience would have
the financial clout to go there I suspect. That vertical dipole tip
would have to be hoisted quite a distance to see that the bottom tip
wasn't buried in the earth.

The next problem is height (again) and how it contributes to (or
subtracts from) gain as that varies. There is no "similar" comparison
between the two. You could model and present variations on horizontal
dipole elevation alone for two hours, much less both of them.

Rule 1 of presentations: Don't give them off the cuff unless you are
prepared to follow the surprises.

Rule 2: If you are willing to follow the surprises; then you aren't
really giving a presentation.

I had a look at that article, and have concerns about many things stated, and the way in which the author distances himself from some of what is said.

The effect of linear loading is that the contribution to radiation of current in a segment of one section of the linear loading is offset to some lesser or greater extent by the currents in parallel segments. The heat loss is incurred by the current flowing in all the conductors, but the radiation effect is diminished.

This mechanism can increase the loss resistance more than it increases the radiation resistance.

This is contrary to the widely held view that linear loading is essentially lossless.

Owen

That's because the energy radiated at lower angles with vertical
polarization is actually absorbed and dissipated in the ground, while
very little of the horizontally polarized antenna energy is.

Tom Rauch, W8JI, has the capability to run some pretty good comparisons
under near-textbook conditions, and he's consistently observed the same
thing on 160 and 80.

> strength in both transmit and receive?

The short answer is that I don't think anyone really knows. I'm convinced that the program accurately calculates the field from the antenna and environment specified by the model. But there are some pretty significant ways in which the model doesn't represent reality. EZNEC uses the NEC ground model which is highly simplified - its ground is perfectly flat, homogeneous to an infinite depth, and infinite in extent. Real ground is curved and stratified with many layers of sometimes highly differing conductivity and permittivity. Besides the deficiency of the ground models, there might be some interesting phenomena like ground wave energy following the ground for a while, then launching some distance from the antenna. This wouldn't be modeled properly by EZNEC or NEC. And although polarization is rotated during ionospheric propagation, maybe there's some inherent advantage to launching a vertically polarized signal. EZNEC and NEC make no attempt at modeling propagation. Anecdotal evidence seems to find more of a disparity between model results and observations at low frequencies (80 meters and below) than higher frequencies. Whether this is due to the greater ground skin depth at lower frequencies, different propagation effects, or maybe just the vagaries of anecdotal reporting, is something I don't think anyone knows.

If the splice will be under strain, a Western Union or Lineman splice
(http://workmanship.nasa.gov/lib/insp/2%20books/links/sections/407%20Splices
.html) is "bestest". I use such splices when there is nothing (i.e.
insulator) to take the strain. IMO, the OP's description of his splice
would not require such tensile strength. In his application, anything that
prevents oxidation of the mating surfaces would suffice.

Art,
I am convinced that you are experimenting in an area of antenna practices that has been neglected... I am always interested in advances on the art and practice of antennas... You hereby offered the opportunity to drop by my qth with your reduced size 160 antenna... If transportation is a problem I will fly my airplane to your area and bring you back to Michigan, or arrange other transportation for you at my expense...
I will personally mount your antenna at the top of a 150 foot tower and we can measure the near field intensity and far field signal strength developed by the antenna, compared to my normal size antennas which are off another tower at a distance .. I am sure I can convince a few of the regulars on here to be on the band and be ready to participate with signal strength measurements, spectrum analyzers, etc... This would form an excellent basis for an article for you to publish - complete with reports from third parties - on a major advance in the theory and practice of antennas...

If I am not convenient to you then I suspect that W8JI or others would offer a similar testing range and I still would be happy to provide transportation just to be a part of an exciting new chapter in radio experimentation...

cordially,
denny - k8do

That is very kind of you but there is no need for any all out effort
regarding travel. What I will do is look around for some copper scraps
and make one for you and use the normal mail. Since I will probably
be
using scrap that I can find my guess is that it would behove you to
use
500 watts or less for your playing around.
I will send it off about 14 days or less from now and hopefully the
weather will be warmer for you.If I don't find any scraps then I will
send the one on the tower even tho it is not of the optimum design use
can use it as is on different bands. At the moment I am making one
that
can fit into a trouser pocket so that may be the one you get.
Best regards
Art Unwin

Richard, thanks for the comments. Yep, I thought of the thing about the model versus the inverted L mentioned after I had already sent the message. What I should have mentioned is that the EZNEC pattern for the inverted L showed lower gain than the vertical dipole.

As for the anecdotal evidence thing: It's my observation. My 756ProIII S meter may not be a calibrated piece of test equipment but the deflection of the needle was much higher while listening with the inverted L. While I can't give an quantitative number to the difference in strength, I can say qualitatively that the Inverted L provided a much stronger and clearer signal.

As for the presentation, that is why I'm here asking the question. No point in putting out info if it is going to be bogus. I saw a discrepancy between my experience and the text books. I'm just trying to resolve that.

Thanks again.

Hi Gary,

Experience is often the most confounding experience you will ever
experience.

After all, does experience explain the angle at which you
receive/transmit that portion of signal in a circuit (the jargon for
connection between you and that distant operator)? NVIS can hammer a
vertical, if that is what you want; even if you forget to lift the
horizontal into the air. So a horizontal dipole on the ground is the
best antenna compared to the best vertical? Not when you shift bands
and target a DX station.

Does experience explain the difference in (at what would be a strain
to justify) "a vertical at the same height as a horizontal dipole?" To
fill in that last parenthetical: What makes a vertical dipole at an
EQUAL height to a horizontal dipole? The equal high feed points? The
equal highest point of metal? The equal average height of both?
Choose any one of three and the other two could have better
performance over the other - and still someone in the audience could
cry nothing can be said to be EQUAL.

Does the experience at 160M with a ground mounted vertical translate
into the same experience at 10M? Experience in the 'burbs with trees,
homes, sheds, cars, playsets in the vicinity would suggest no. An
antenna 16 times taller can see over those same things which are
barely dimples to the field.

A head-to-head comparison will quickly resolve; but as this is an
amateur society with limited antenna options and a multitude of band
choices, experience will often roller-coaster between disappointment
and elation - and as so often proven in threads of amazing inventions
here, those inventors demand classical text books should be discarded
as being obviously counter to "experience."

The emerging new invention of an 160M band antenna the size of two
shoe-boxes should show how plastic and flexible experience is such
that it can stretch to fit into a suit 300 times it size.

Thanks for the info, Lamont. Well, it's going to be difficult to get
that
90 deg angle at the central feed point, since the 'dipole' will be
something
like a 10-meter long magnet wire hanging from my balcony with a weight
at the bottom. I could run coax down alongside for 5m and have it
connect
there in the center.

Hmmm...wonder if a Buddipole clamped on my balcony railing and
pointed out at a 45 deg angle will work better for me.

Thanks,
~swooz

Make it 5 meter long wire hanging from the center conductor of a
hanging 5+ meter long coax.

I suggest that you take pains to make sure the feedline is well decoupled - a couple of current baluns, one at the feedpoint and one a quarter wave down the line, should be adequate. An extra measure would be to measure the common mode feedline current to make sure it's minimal. That would go a long way toward silencing critics (like me) who believe that reported good results from such small antennas are often the result of feedline radiation -- that is, that the feedline is the primary radiator and the "antenna" plays only a minor role.

Or fold 1/4WL of the braid back down over itself leaving
1/4WL of the insulated center conductor to hang down.
It's called a sleeve dipole.

Thanks Roy, but darn, I was hoping that was not the answer. I was hoping this was a subject someone had worked through definitively. Oh well. What counts is how well an antenna works, not what calculations show.

At no point did I think that EZNEC and NEC2 were busted. The output I saw matched expectations arrived at from digging through text books and scientific papers. I was eventually looking for a clue as to what the NEC2 algorithms might be missing. I found the "leaky ground wave" thing for lower frequencies an intriguing idea. I expect that above about 10 MHz, where ground wave propagation becomes a fairly minor consideration, NEC2 should provide a fairly accurate prediction of vertical antenna performance.

I understand all that. If Tom wishes to add one for his
own satisfaction that's fine by me.
If he wants to test it then I am confident he will do what

ever is necessary without comment from me.
I have no wish to influence him in any way. He cam make his own call
even if it means that it burns up. I have no experience with 180 M
and have only loaded it for 100W. As I have stated before, I have not
been active for years because of illnesses etc and I would not
presume
that Tom would need any assistance from a blithering idiot and
liar such as I.
W8TI Tom laughed his socks off when I mentioned resonant tank
circuits
in equilibrium and refused to give me any time for discussion.
On the other hand, Tom in Michigan has always been polite to me
and appears to have a genuine interest in new ideas, so I have
worked all day today in getting things together so I can get
one to him as quickly as possible.

I suspect that the EZNEC program is not designed for taking into account such "rare" phenomena as "ground wave propagation". So much for EZNEC analysis at 75m.

Instead of pulleys, I use large screw-in insulators like you might see on a
power pole. They are slick enough to act as pulleys, large enough to take
two ropes (one for the continuous loop and the other for holding the
antenna), they don't cost much, and a rope NEVER jumps out of the
"pulley"!

I've also used a screen-door spring (or two in parallel) between the rope
and the end-of-the-antenna insulator (with some more rope in between
so the spring doesn't add much capacitance to the antenna proper) to
give some strain relief.

hi

pretty soon when current tv broadcast stops i was thinkng my
building master ant will either be left there or just removed

i thought about petitioning the coop board to let me have the space
under the guise of replacing the antenna with another that looked for
the most part just like/simular to the old tv ant but actually
subsituting a ham antenna

my first thought as far as a look alike was to a LP , just
wondering of all of the antennas out there anyone know which specific
brand might come closest to looking like a regular tv antenna?

thanks

2263. far radials for verticle?

Date: 2008-02-15 11:09:05 UTC
From: ml <m@di.net>
Message-ID: <m-DB9107.06091415022008@news.verizon.net>
Source record: 28085

hi

I might be able to get permission to put up a simple multiband verticle

i'd have to mount it on the elevator room (brick wall 10ft high) of my building.

if i got approval, the coop board wouldn't let me put 'radials' off the base of the antenna they don't like the way it'd look

The roof floor is concreat w/tar then small stones

wondering if i could just burry lots of wires and attach to the bottom of the mast, so it would be 10ft away from the base of the antenna, which would be held onto the wall w/a 10ft mast not sure how that couples but i presume it's base of antenna not base of mast that counts

how bad would placing the radials be in this manner (all band verticle)

are there any other alternatives?

the roof of the elevator room is 10ft by 10ft i could put 1 or 2 wires on the base /floor of that but it would all be in 1 compas direction mostly

not sure which is 'best'??

any tips appreciated

thanks

2264. Re: Arrl antenna book cd does not install, help

> particularly the previous edition of the antenna book that, according
> to what someone said on this newsgroup, should be contained in the cd.
> Thanks a lot in advance

the disk dosn't have to really install, just the viewer program,
most people just either explore it as mentioned or use the arrl
program to navigate /view it

you can of course put the entire cd on your hd if you like

just treat it like any other file, copy the cd image or the entire
contense to a new folder on your computer

then try to get their viewer working it should install, since you
didn't mentioned why it didn't install i can t say more what error
messages did you get?

you can also perhaps call arrl they may be able to walk u thru a simple
install or a tech issue w/it not installing

most of the files are common files there you should be able to view
them even w/o the arrl program however it makes it easier

good luck

Source record: 28087

Those radials are the 'other half' of the antenna, so having them
'close' to the first half is sort of reasonable, right? Then there's
the 'can't get there from here' problem. So, the 'trick' is to get
around that 'problem', and there are a number of ways of doing that.
None of them are 'best' by any means, but still do-able, sort of.
Since the objection is a 'don't care for the looks' thingy, one method
is to hide them in some way. Run the radials from the base of the
antenna, then cover them so that they sort of 'blend-in' with the
surroundings?
Lumping all the radials on one side or the other tends to make the
antenna sort of directional. Maybe not a 'good' idea, but certainly
better than no antenna at all?
Imagination!
Good luck.
- 'Doc

Hi Myles,

Any Log periodic that looks like a TV antenna is going to cover
VHF/UHF - keep that in mind if you are hoping for HF.

However, nobody sees those antennas way up on the top of your building
except the traffic spotters in helicopters. If you want to sneak an
HF LPDA up there, then you will need a tad more height for masting,
and more than a tad more support/guying.

My own experiments with vertical vs dipole led me to the conclusion that they both work better than the other, and they both work worse than each other.

I based my analysis on signal strength using a db pad to match for the weakest signal vs the strongest one. You can't do this one with just the S-Meter, they aren't very accurate.

Sometimes the vertical "worked" better, and sometimes the horizontal did. And while a generalization could be made for distance, therefore "take off angle" between the two antennas, the reception could change in the middle of a QSO, favoring one other the other.

Comparing one antenna against another is quite difficult - at least to say which one "works" better.

And I'm curious - where is the propagation function in EZNEC?

Mike wrote:
"Group Velocity and Velocity factor - Can someone explain how these two relate in a waveguide."

Group velocity differs from phase velocity (which is defined as the velocity at which a point of constant phase is propagated in a progressive sinusoidal wave). Group velocity implies several transmitted sinusoidal waves for which the medium has a velocity factor that is a function of frequency.

Waveguides are used over limited frequency ranges so that their dimensions exclude propagation of any but the dominant mode, and so that the operating frequency is sufficiently above the low-frequency cutoff of the guide to avoid excessive attenuation. The limited tange of frequencies transmitted through a waveguide assures a group velocity ahich equals the phase velocity and thus assures low attenuation.

Terman explains the above in his treatment of "Rectangular Waveguides" which begins on page 128 of his 1955 opus.

Sure, if you can live with the mismatch. Better if you can tune it
for one band. Or simply stick with my suggestion and run it into a
tuner which you will probably need anyway. The difference between any
of these will be undetectable at the far end of the QSO.

To reduce the chance of a hot chassis due to common mode currents, you
should use a 1:1 W2DU style BalUn (aka choke).

There is none, of course. You would have to construct the lobes on an
asimuth chart but this is only useful for take-off angle and skywave
propagation. EZNEC information tells you nothing about ground wave
propagation.

Two things wrong with this:
1. EZNEC does provide information about the radiation characteristics
along ground at any distance on an infinite, flat plane and at any
elevation above it;
2. EZNEC is not a propagation modeler as its users are well aware;
3. EZNEC models the 100M work of Brown, Lewis, & Epstein quite
closely. There is nothing in the body of RF literature to suggest
that the nature of radiation shifts suddenly in 7/8ths of a megahertz.

I've found that the trick of folding the braid down over the coax does a very poor job of decoupling the line in an imitation of a "sleeve" or "bazooka" dipole. It turns out that you really need a high Z0 for the decoupling sleeve, and the only practical way I know of to do that is with a larger diameter pipe, and air insulation between the pipe and the coax. I've also found that a choke balun made of multiple turns on a single core, by itself, anyway, doesn't provide adequate impedance. I'd worry that a W2DU style balun would cause a lot of loss in this application, but it should be possible to model it reasonably well with a series of loads and find out. (You'd first need to determine the actual Z of the type of core used, at the operating frequency.) You might be able to decouple the line adequately with a very high impedance and low resistance resonant current balun (common mode choke), perhaps one made by winding coax on a plastic pop bottle. You'd probably need a second current balun of some type about 1/4 wavelength down the line. My experience is that it's a trickier problem than most people think.

Art wrote:
"My present antenna, which is for 160 m and above, is about the size of two shoe boxes and is less than 2:1 swr (50 ohm) across the band when situated at the tip of my tower."

Outstanding! An effective antenna needs to be an appreciable portion of wavelength in some dimension.

If Art`s antenna is an appreciable portion of 525 feet it can radiate well on 160 meters.

Any length of wire carrying an RF current is capable of radiation. Significant radiation from a short wire requires much current.

With a garbage can lid for a reflector, a helical antenna can be made. Were it 3 feet across in diameter (0.9 meter) the helix might work on 3 meters as the diameter needs to be about 0,3 lambda. Terman gives helical antenna information on page 909 of his 1955 opus. His best bets for small antenas are the corner reflector and the Yagi.

This is demonstrated everytime a pulsed radar fires. Energy for the
next pulse is stored in a Pulse Forming Network that is either a
transmission line or lumped circuit representation of a transmission
line. High energy devices such as radar, lasers and xray equipment
often use the lumped circuit (LC ladder)representation of a
transmission line to store energy. I dont know if there is a practical
example of an actual transmission line being used for this purpose
outside of a design laboratory due to physical impracticality but
under those lab conditions it was discovered that an actual
transmission line provide a pulse of superior shape than the lumped
circuit PFN. It should be noted that when a radar fires more power is
taken from the PFN in say 1uS than was placed into it during any uS
while the PFN was charging. MIT/ Lincoln Labs is probably the best
source of data for anyone who wants to research this further. The use
of a transmission line to store energy is covered in just about any
introductory level radar theory book.

For quite some time now I have followed this thread(s) wondering if
all the arguement is about whether or not a transmission line can
store energy or not. If this is in fact the question then the answer
is definitely YES.

****
Yes, but it is not useable if C and L for the length involved and
frequency of use is not adhered to.
Implicit in Maxwell's laws is that a radiator can be any size or shape
as long as it is in equilibrium. Without the inclusion of that last
word
all laws of the masters are invalid.

#######

It is not the physical size that is important whith respect to a dish
it is the wavelength between the two objects that counts. A simple
helix
antenna can use a reflector in place of a ground plane not as an
optical
ray deflector.Such an array is not in a state of equilibrium

Joules of energy delivered to the standing wave during the
key-down transient state can be enormous when very high
SWRs are involved. When key-up occurs, that energy has to
go somewhere. More than ten times the steady-state power can
easily be delivered to the load during the key-up transient
state.

Yes, there is no abrupt shift at 75m (most obviously). Quite simply, as you
approach larger wavelengths, skywave characterstics lessen and groundwave
characteristics increase.

But I am a heretic for not having mindlessly bowed in adoration at the altar
of the EZNEC god in blind faith as you and others have done. However, those
fanatic evangelists who live by blind faith alone have wisely plonked me so
as not to let their blood pressures rise at the spectre of the EZNEC god
being angered.

The little program I wrote and referenced a little while ago, TLVis1, shows graphically how much energy is at each point along a line at every time from turn-on to steady state. And it even shows separately how much is stored in the electric and magnetic fields.

That's always interesting - and usually without a good explanation.
I don't know how many times I've switched from one anntenna to another just to have the quote"inferior in theory" antenna get better results than the "better" antenna.
Antennas are magic. There may be a metal building or some near-but-out-of-sight tv antenna mast or tin roof or aluminum-foil-lined insulation giving some directivity.

Hi Dan,

Heretic? More Arthur's heathen love-child. Heretics, afterall,
reject the scripture they've studied to present alternatives.
Heathens' marginal knowledge is a limited skill for making soup from
missionaries. Run out of missionaries and heathens starve; at least a
heretic can scrounge up a meal by holding out a hat on a street
corner.

Do you claim to have a hat?

You may have issues with Roy, but it is pretty unprofessional to deride his program on that account.

It does predict the angle of maximum radiated power. "Take off angle" is a great term for those who believe that the energy exits the antenna as a blob, all in one place, and no energy elsewhere.

It isn't a propagation tool, it's a design tool, and as such propagation is not at issue. Apples/Oranges.

But you're a smart fellow, so I guess you are pulling our collective legs here.. 8^)

Strange, ain't it? This guy starts out kind of reasonable, and within
a month or so turns into a newsgroup nasty...

Who's standing up for Roy anyway? He didn't put in propagation
effects in his antenna design program? Horrors! Makes me think about all
those fish without banjos out there.

While we're on the subject, I always wondered why EZNEC didn't
include a decoder for PSK31!

Hopefully the sarcasm was obvious to everyone!

> - 'Doc

hi

thanks for the responce

one question i ponder , o is the 'base' of the antenna (my verticle)
considered the part where it meets my support mast

or the bottom of the support mast?

normally the manufactures radials are at the base of the antenna
and the support mast is physically below that but not sure does that
rf decoupple the metal support pipe?

if i can claim the base of the support mast to be or make it "" be
the bottom then that is near the roof surface and very easy to hide
wire radials in all but 1 direction

the other thought i had is since the wall is 10ft high if the
'base'' is considered the bottom of the antenna (not the support
pipe) then i could run wire radials from there draped over and
down the elevator room then flat horizontal so it would look a
little like a pealed bannana i can then burry the radials at
roof level in all directions

just trying to figure which is the best way to work around the problem

thanks again

> Doc's advice covers the antenna. Did you solve your problems with the
> elevator control noise? Tell us that story.
>
> 73's
> Richard Clark, KB7QHC

hi

good to hear from ya

unfortunately not too lucky here , i went up to roof sluthing around
w/my analyzer and 817

i sure heard and saw 'noise' i know for sure the elevator room is
throwing out noise

can't yet absoluetely say it's the elevator thats causing my
specific noise sure seems likely thou

i still havn't figured out how many turns to make around my 2x2' X of
26ga wire insul, as i see i will really need a very directional
antenna to pinpoint

seems very easy now to say what seems obvious but doing the actual
finding scientifically is harder then i thought due mostly to my
poor skills

i also when taround the block trying to figure if a lamppost or
inground xformer was noisy but didn't seem soo

only thing i can say for sure is i have s9 noise from 1-15mhz and
maybe s6 from 15mhz to 30mhz and it's seemingly randomly intermittant
off a few min then on a few min or so

i am going to set up a portable 80verticle i have in the bedroom
w/the rig to see if maybe the noise is comming from an adjecent apt

i think i have enough test gear but sorta not sure what do to
track the noise down , never really did that before as far as
specific professional methods and procedures

yet i suspect it's something rather obvious throwing off the noise

i also wonder if it's possible that something in my sgc237 could have
failed such that it would make that noise? it gets prety def when
power is removed so not sure w/that attenuation i could tell and i
can't really sub another at up there i just don't have access to
the roof to easy

i sure do miss hf thou

hi thanks guyes for responding

i should have specified HF

don't need anymore height the tv antenna is over 10ft from roof
surface and they wouldn't let me add to that

i could get away w/a somewhat bigger antenna but not 'super large'
i was thinking if it looked like a tv at, and was even 2x the size
perhaps no one would really notice

so i've never really seen any lp face to face and wasn't sure
about of all the ones made which might be closest at fitting the bill
was hopn someone might be familiar w/a specific brand/make /model

etc??

thanks much

Hi Myles,

Trust your instinct on this one = it's the elevator motor controls.

>i still havn't figured out how many turns to make around my 2x2' X of
>26ga wire insul, as i see i will really need a very directional
>antenna to pinpoint

I'm not sure what to make of that. Just use a small SW receiver with the whip pulled back into the set. Smaller the antenna, the closer you have to get to the noise. The closer you are, the more obvious the source.

>seems very easy now to say what seems obvious but doing the actual
>finding scientifically is harder then i thought due mostly to my
>poor skills

Your skills got you to the source of the problem, the difficulty is more your coming to terms with how to solve it. You aren't going to get into the elevator control room to fix anything - even if you knew what to do. Management isn't going to spend money to fix a problem that doesn't bother them. Ask your neighbors if they have any TV noise issues that just started - get allies. Think about it, if they complained about your HF rig messing up American Idol and the building super came down on you; then they could as easily demand he fix the elevator for messing up American Idol too.

>i think i have enough test gear but sorta not sure what do to
>track the noise down , never really did that before as far as
>specific professional methods and procedures

Time to look into the gear that does noise canceling. We get a number of posts here from those who find relief from just your kind of problem. All it takes is an outboard unit with its own very small "sniffer" antenna (probably not any bigger than a short 3 foot whip for your purposes). Twist a couple of controls and the noise plunges to S3 or so. Maybe someone in the group who knows the vendors can suggest something here.

Hi Myles,

Think of that TV antenna being roughly for 2M. Now think of your
antenna being for 20M. Your HF antenna is going to be 10 times
larger, and it is going to need to be further from the roof for the
same reason (nearby clutter is going to be in its field of view - so
to speak).

Roy decided to ploink me because he was not able to follow a reasoned technical discussion. Roy is kind of funny that way, he is very impatient if you question whether he is right or wrong. Roy is always right, by definition. Anyway, I told him, "fine you can ploink me but now you won't be able to see my posts and defend yourself when I begin highlighting the things that EZNEC CAN'T do (many hams consider it the be all-end all but it has severe limitations when it comes to the actual use of your ham radio).

Is there some part of "infinite, flat plane" that you fail to understand?

EZNEC provides horizontal, vertical and 3D radiation patterns. Is there
some other dimension you are interested in?

Which are functions of propagation, not antenna modeling.

Hi Dan,

"EZNEC can't whiten my teeth" sounds like so much of your naive
whining; why would ANYONE put any effort to "defending" against that
kind of boorish trolling?

Well, obviously I do. When technical content is so lacking in your
complaint, all that is left are the humorous gaffs like:
>>>EZNEC does provide information about the radiation characteristics
>>>along ground at any distance on an infinite, flat plane
>>>and at any elevation above it;
>>
>>Really? Can it follow the curvature of the earth
where the distance between "flat plane" and "curvature" are separated
by only eleven words - a netzheimer's record for cognitive fading.

After all, as you are one of my groupies, you were trolling for this
response weren't you? ;-)

I didn't make that gaff, that was someone else ;-)) I happen to subscribe to the belief that the world is round. I understand that even most flat earthers don't consider it to be an infinite flat plane, otherwise they would reason that the sun wouldn't be able to rotate around it.

Get my gist? Does this help you understand a little bit more about ground wave propagation and why hams should not use the above EZNEC assumption in designing vertical antennas for the longer wavelength DX? Like maybe, the curvature of the earth "happens"? ;-))

Thats probably because both antennas can be made to incredibly slack
tolerances and still work quite well. I hacked together a Quagi for my cell
phone a few years ago while camping that worked beter than my factory made
yagi.

Technical content noted. I am going to seriously reconsider my participation in this newsgroup. Too many people here do not wish to discuss real science, they just want to argue and flame. I have seen many times here where a person makes an assertion that I know is true, even by use of such elementary tools as a smith chart, yet yahoos who know nothing about engineering try to shoot the assertion down in flames based on personality differences or whatever. Defending such assertions that are based on first principles violates the politics of the alleged gurus. It all reduces to a non-technical word game (semantics becomes the norm) where the search for scientific truth and understanding is suborned by personality cults and word games. And oh, by no means must anyone *ever* question the EZNEC software tool! My god, software is scientific perfection itself. However, when the Apollo made the landing on the moon I wonder what would have really happened hadn't Niel Armstrong assumed manual control of the craft at the last moments? So we have the software addiction of antenna modeling and we find the author of this thread puzzled as to why he cannot explain to his class the problems associated with software modeling in conducting real world QSO's. Try to explain and wham! You get hit. You are a heretic. On the other hand, you have some crackpot trying to explain antenna theory as quasi cosmic particles spewing out of the ends of a shoebox sized antenna and you have a private pilot offering to fly over to his QTH and test the new concept. I am at all loss to how real scientists like Cecil Moore and Gene Fuller can continue to participate here. I think I will just stand by and lurk for a while and if I see no changes, I will simply write this off as a flame group and go someplace else like eham.

Hi Mike

I have some limited accuracy test equipment for evaluating antennas.
Recently Richard Clark prodded me till I couldnt take it any more so I got
some of Roy's software. Richard even told me how to use it. It has become
clear that *my* test equipment is is very good agreement with Roy's EZNEC.
. EZNEC works so well for my situation that I thought it was woring well for
everyone. I can make real radiation patterns of my prototype antennas
(using POES signals for the illuminator) that are in agreement with EZNEC
prediction. Even the inpedance of the eklements are well predicted by

EZNEC. Do you know where any real data is in disagreement with EZNEC predictions? I'd like to know more about any data anyone has that shows where EZNEC gives wrong data.

Jerry KD6JDJ (who is extreemely happy with his EZNEC "tool")

I can't recall offhand, but I think there are a few instances in which the engine has difficulty. But any softare using the engine would, and for almost any application, it wouldn't matter.

Otherwise, it is one nice piece of software, and functions well and as advertized.

Possibly embarrassing accolade follows.......

We are lucky to have someone like Roy posting here. So many truly competent folks have been run off from the newgroups by the crazies over the years that people like him are becoming more and more rare.

No, it's 73 de LAWRENCE COUNTY AMATEUR RADIO ASSOCIATION, right "Mike"?
Check N3LI on QRZ.COM) http://www.qrz.com/detail/N3RI. And then tell me
that their direct reference to the FCC database got it wrong. Does the
trustee "Cliff" know you are using the "club" callsign?

Note: Better tell your "club" that it's call sign expired in June 2007. And
you tell *me* about fringe groups? Just what do all the guys in your "club"
do to pass the time since you can't get on the radio anymore? Shall I
inform "Cliff", as trustee, how badly you are abusing his call sign, or are
you really "Cliff". The mystery deepens....(hi hi)

2319. Flagpole J for 10 Meters

Newsgroup: rec.radio.amateur.antenna
Date: 2008-02-17 03:18:28 UTC
From: Jimmie D <GFENDER@carolina.rr.com>
Message-ID: <47b7a783$0$1084$4c368faf@roadrunner.com>
Source record: 28041

I was reading in the Vertical Antenna Classics book an ARRL publication and I noticed an article on a 10M J antenna that seemed a little strange to me. The overall length of the antenna is only 1/2 wl including the stub. I thought they were suppose to be 3/4 wl long.

Jimmie

There are many very serious commercial users of EZNEC who have the capability to compare its results with professionally made measurements. They regularly report very good agreement -- if the agreement wasn't good, in fact, they'd certainly quit using it. You'll find antennas designed with the help of EZNEC on military and civilian vehicles, aircraft, and satellites, in use by domestic and international broadcast stations, and countless other places as well as in many, many amateurs' back yards.

I can't take credit for its accuracy, however. The basic calculations are done by NEC-2, which has been even more extensively tested and shaken down for several decades now. As a result, its limitations are quite well known and documented, and I've tried to pass these along in the EZNEC manual, correspondence with users, and in postings here. NEC-2's ability to accurately predict antenna performance is also very well known. NEC-2 uses some very fundamental equations which have been well established by over a century of theory as being those which all real antennas abide by.

But when using *any* model, including the models we all use in circuit analysis -- resistance, inductance, capacitance, transmission lines, and many more -- you always have to keep in mind that the analysis applies to the *model*, not to any real object. So the results are only as good as the match between the model and the physical circuit, antenna, or object the model represents. Anyone not able to recognize when and where a model differs in any significant way from the modeled object shouldn't

be using modeling for analysis, because his results are bound to be wrong and he won't know it. On the other hand, one who recognizes the differences can still often get useful information from the model even though it might not fully represent the actual antenna. As just one example, I've recently been designing a number of antennas which are fabricated as traces on a circuit board. They have requirements for pattern and SWR bandwidth, and have to share a fairly small board with one or more other antennas and a substantial number of other conducting objects which aren't electrically small at the operating frequency. Although EZNEC has no way to accommodate the effect of the dielectric (which is quite significant), it has nevertheless given critical information about interaction among the antennas and other conductors and its effect on pattern and bandwidth, allowing me to optimize my designs for adequate performance in the difficult environment. I've produced designs which have worked as intended with only a minimal amount of modification. Several are now in use in the client's products, and they keep asking for more.

Models can be made for many antennas and systems which represent the real antennas or systems to a very good approximation, and those will agree very well. The ground model is a weakness of NEC-2 and therefore EZNEC. Fortunately, it's still good enough for all but a relatively small number of applications. Making the ground model curved according to the Earth wouldn't make any real difference in results except for extremely high antennas or for ground wave communication at distances greater than about 100 km. Perhaps the greatest shortcoming is the homogeneous ground assumption, which can be very different from real ground. I'm not convinced that a single "equivalent" homogeneous ground can be found which behaves like real stratified ground(*). But the skin depth in average soil at 1.8 MHz is about 20 feet. So to properly model it would require the ability to include strata extending perhaps to 60 feet or so. And even if you added this capability to the program, how would you measure the ground conductivity and permittivity at all the necessary levels, to that depth, over the area necessary for calculation? And how about hills, houses, buried water and power lines, and roadway rebar?

So, like any other tool, today's modeling programs don't do everything. But in the hands of someone with a basic understanding of their applications and limitations, they can be a tremendous tool, solving in seconds problems which were beyond the capabilities of the very best engineers and scientists just a short while ago.

(*)AM broadcasters determine an equivalent ground conductivity by measuring the ground wave attenuation of an AM signal. However, this is equivalent only in that it results in the same attenuation. The effect of the ground on a radial ground system or far field pattern might be affected differently, and require different "equivalent" values. But it's possible that no "equivalent" would correctly predict, say, an elevation pattern from a vertical radiator over stratified ground.

Ahem.....

I'm N3LI. Its true, I swear! I looked it up in the database, and was
pleased to see mine very own name.

You wrote:

> http://www.qrz.com/detail/N3RI

Ayup, * that * will give you the group in Lawrence County.

Feel free to tell "CLiff" about my malfeasance! Might as well tell Riley
that someone is masquerading as someone else by using a callsign that is
only 6 letters away from his actual one too! What a trickster I is....

> Note: Better tell your "club" that it's call sign expired in June
> 2007.

I'll pass, though you might if you care. I suspect that they might
have let it expire, as the FCC is trying to cut down on the groups who
hoard callsigns. Lawrence county is probably just doing the right thing
here. Its also possible that that group doesn't exist any more. I can't
find a reference online.

> And you tell *me* about fringe groups?

Ayup.

> Just what do all the guys

My guess is that the Hams in Greencastle use NC3LC as a club call

Shall I inform "Cliff", as trustee, how badly you are
> abusing his call sign, or are you really "Cliff".

Oh would you please? I might be a little suspicious of that other group
in Lawrence County also with their club call of NC3LC. After all, if you
drop the first C from their callsign, and add 9 letters to the last C,
you'll come up with that N3LI callsign again.

Here's one where all the geometry and segmentation checks
are OK but the conductors are too close together. It results
in an omnidirectional antenna with a 24 dBi gain.

Hi,

In the case of PUSC permutation mode of OFDMA, why do they adopt the
policy of renumbering ?
I searched the internet, but i do not find any specific link/doc that
talks about this in detail.
Any ideas ?

Thx in advans,

Hello Jimmie:

Make the antenna 5/8 wavelength long, they just work great at 5/8 wavelength long. Run some wire for the ground plane radials. Its not hard to add in a wire matching system.

I built a 20 Meter 5/8 wavelength ground plane at 41 feet tall (not for the faint of heart and normally minded people) but it worked better than expected.

Jay I was concerned about the discription in the book I had never seen a J antenna that its total overall length was .5 wl, The ones I am familar with are .75wl long. Back in the early 70s a friend had put up a 100ft tower and had to wait quite a while for a crane to set his antenna. To get him on the air in the mean time we put a .25wl section of water pipe .5wl from the top of the tower and turned it into a J antenna. Yes this was for CB. The overall length of this antenna was 3/4wl including the stub. I had never seen a J antenna that had an overall length of .5wl as described in the book. I was just wondering whether someone seriously screwed up or what.

Hello,

New at this.

I guess radio waves can go through wood just fine, as I can har signals from my Discone that's in my attic.

But, there is, I imagine, some attenuation as a function of type, thickness (of the wood) and the frequency involved.

Are there any good links explaining Attenuation as a function of frequency for different materials, etc. ?

thanks,
Bob

Hi Bob,

Yes. I've even calibrated products that measure the percent moisture content of wood using RF probes. However, most of what you might find is in terms of nearfield (much like my probes); or as forest. Of course, the attenuation of 2x4s falls somewhere in between, but I would hazard to guess, it doesn't amount to much.

Nearby trees, on the other hand, do represent a significant wavelength of wetter wood (dry wood is about 15-22% water, and standing wood is significantly wetter). We have, in the past, found postings here on how to drive a nail into a tree for a feedline connection, lay out radials, and use the tree as a radiator for HF. I suppose it was as efficient as a 160M antenna the size of two shoeboxes. That is to say it is not so amazing that it works, as it is to say that someone tried it.

When you consider how much bulk wood is in a house, and how much volume the house occupies, the loss would seem to be inconsequential at HF. As you mention a Discone in the attic, I must expect you are more concerned with VHF/UHF. This will alter the loss landscape, and I doubt there is a lot of accessible data about wood's loss in those bands as it is so easy to avoid (putting an antenna near timbers, that is).

I think that I'm going to start with this idea, since I have a radio coming in the mail and would like to do the simplest and cheapest up front to get the radio tested out. I have a few questions:

1. After I wire up the antenna & coax as described above, can I do my trimming to frequency by using only the radio's SWR meter, or do I need an external tuner at the wire?

2. This radio can output 100W on HF. Can't this setup with a 10m length of 26-gauge magnet wire handle this?

3. I may need to run up to 30' of coax. What type should I buy?

Thanks for all the help!

Wouldn't you need 2 flagpoles to get the lower part of the "J" up in
the air? Maybe the stub is on the dirt.

The lower 1/4WL of a J-Pole is a matching section and
ideally doesn't radiate. It can be turned horizontal
so the antenna height is only .5wl. Is that what you
are talking about?

One thing you should realize about the half sloper is that it's only
half an antenna. The outside of the coax, in your case, is the other
half of the antenna. If you put one amp into the "antenna" wire, one amp
will flow down the outside of the coax. So don't be surprised if you
find strange effects in your shack, such as electronic keyers which keep
sending, push-to-talk buttons that turn on the transmitter but don't
turn it off, RF burns from the microphone, and an SWR that changes when
you move the feedline around or change its length. You might get lucky
and not see these effects if the length of coax to the antenna and from
the rig to the ground is favorable, or you might not. You'll also need
to take care to keep the feedline as far away as possible from power or

telephone wiring because it's radiating just like the "antenna" part of the actual antenna.

For those reasons it wouldn't be my choice for an indoor antenna, but apparently Yuri has gotten lucky and had success with it, and so might you, too. I'm sure you'll get some other suggestions from people with a lot of experience.

26 gauge magnet wire is fine for most indoor antennas (about anything except an electrically small loop). RG-58 is fine for the coax, up to a few hundred watts, if the SWR is fairly low. If the SWR is fairly high (say, above 3:1) and you're running 100 watts, you might want to use RG-59 or RG-58x instead.

Have fun!

Cut the wire long, and trim by small increments. If you are still
trimming well after it is obviously shorter than a quarter wave,
further trimming might find resonance, but you could be bucking up
against unknowns (this is not likely to be big problem however).

>2. This radio can output 100W on HF. Can't this setup

Common radio shack stuff will work fine. You can spend more,
certainly, but if your antenna is tuned, no one will be able to tell
the difference at the far end between hardline and RG156 (you won't
find that at RS, probably, but there is a lot of RG8X).

However, it you can put up one wire for one band (no tuner? THAT is
odd) you can as easily put up three, four or five as a fan sloper (or
dipole, or monopole...) and not have to worry about SWR for one band
or several. It takes only slightly more construction ingenuity and
effort, but perhaps it may be too much visual exposure that draws the
unwanted eye (which, I suppose, is why you are using magnet wire in
the first place).

Not as bad as foreseen.
What the HalfSloper is - vertical or ground plane antenna turned on the side/angle and the pattern then formed between the antenna and the ground reflection.
It is beneficial to connect as much "iron" as possible as a ground plane - guardrail, door frame flushing. The RF is then formed between the radiator wire and the "ground plane" with little getting behind it. Just to underline that sloping wire goes away from the building, not anywhere inside.
You can use SWR meter on ic706 to find where the wire resonates and trim it to frquency. It should be close to 50 ohms, you should not need a tuner. I was expecting my setup to have lower impedance than 50 ohms and had coil ready, to be inserted between the guardrail and the wire and then finding the tap for 50 ohms on the coil, few turns up from the ground connection. But it turned out to be perect 50 ohms and wire length was original vertical wire from my baloon vertical working against 4 elevated radials on 160m.

I had no problem with RF, coax was about 8 feet between balcony and rig and computer next to it. In case of longer coax and to be safe, you could wind few turns of coax in a coil at the feed point to form the choke.

It is outdoor antenna with pattern being formed between the radiator wire and metal mess of the building, RF stays outside with reasonable amount of "iron" and wiring in the building.

I would use 50 ohm coax, RG 58 variety should be OK. 26 gauge wire should fine.

The book shows .25wl of antenna and .25 wl of stub, all made of copper pipe arranged in a linear fashion, total length .5wl or about 17 ft on 10M. I guess no one else here has the book I referenced. This is also suppose to be in the March 1989 QST per the book.

I believe that must be an "Open-Sleeve Antenna"
described in the ARRL Antenna Book on page 7-20
in the 20th edition. The center element is a little
over 16 feet on 10m.

Dan,

I am a real scientist, but I would never dream of attempting "real science" on RRAA. I try to say only things I believe to be correct, as do most people, but this is far more like a blog than a scientific journal. The burden of proof is simply based on who runs out of gas first.

There is some very useful information here along with quite a bit of more questionable lore. There is some trolling. But it is all basically entertainment. Put on your waders and remain skeptical.

Even scientists need entertainment once in a while.

Hi Dan,

I thought you were generally for such things. To what do you
attribute this shift in feelings for science? After all, a cost of
merely $1B and some tears shed for no one yet put to any physical
discomfort when we've spent nearly a Trillion to no obvious gain and
certain death for thousands seems rather a whipsaw out of catatonic
lethargy. Should we turn our eyes toward the South Pole to the
neglect of the national paralysis in the middle east?

On the other hand, focusing on the South Pole, an interesting parallel
diversion of no immediate consequence in these threads, could also be
a way of distancing oneself from other embarrassments of mistaken
attributions.

Have you come to means by which you can reconcile the difference?

Cost of *one day* of the Iraq war: $275 million.

http://www.nationalpriorities.org/costofwar_home

So the cost of the SPT works out to about 21 hours, eight minutes of
Iraq War, and it will certainly last a lot longer than 21 hours. If it
will outlast the Iraq war is another question.

> It will easily approach $1 billion.

...or about 3 days, 16 hours of Iraq War.

Voluntarily. No one faces criminal charges for refusing to go and so
far zero casualties versus 3,966 in Iraq.

> Why? What will
> be the payback? All this money and risk for "maybe" a "potential" clue to

More than that, do a little research and reading before you spout off
and confirm your ignorance,
http://www.nrao.edu/news/Technology_doc_final.pdf

> More government spending gone amok. And we
> wonder why the US dollar is approaching 0.5 Euro.

The reasons for the devaluation of the dollar have all but nothing to do
with what the NSF is spending, you should refresh your knowledge of
orders of magnitude and economics.

> The most expensive radio
> telescope antenna in the world....where is the common sense?

Certainly not in your head. Get a grip on the real numbers and facts
about the Federal budget and the American economy and maybe you'll have
something to say that doesn't sound like some parroted conservative
talking points, a/k/a lies and deception.

To further our understanding of the Universe and how it works is reason
enough.
Basic research always benefits mankind in the long run.
Some things are worth doing even if it does not produce better bicycle
wheels or more money in the pockets of oil companies in the near term.
After all Michelangelo could have used a paint roller on the ceiling of
that church. It would have been cheaper and quicker if he had. A nice shade
of beige would have been OK or maybe institutional green.
Ignorance is not bliss!

Don't forget to dial the phone number below
Cell phone numbers are going public today - This is a REMINDER
All cell phone numbers are being released to telemarketing companies today and you may start to receive sales calls. You will be charged for these calls.
To prevent this, call the following number from your cell phone:
888.382.1222
It is the National DO NOT CALL list. It will only take a minute of your time. It blocks your number for five (5) years. You must call from the cell phone number you want to list.

No, thats not it either, I think someone just screwed up on this antenna.
Stub is 8'7" radiator is 8'7". Built like a typical J antenna its just 8'7"
